

## REVISION OF PHYSALIS SECTION EPETEIORHIZA (SOLANACEAE)

MAHINDA MARTÍNEZ\*

### RESUMEN

El género *Physalis* incluye alrededor de 90 especies que se han agrupado tentativamente en cuatro subgéneros. En esta revisión se trata a las especies de la sección *Epeteiorhiza*, del subgénero *Rydbergis* caracterizadas por su hábito herbáceo, vestiduras de pelos simples, glandulares o ausente, flores solitarias, corola rotada amarilla y cálices del fruto redondeados hasta fuertemente 5-angulados. Se reconoce 14 especies que se distribuyen desde el sur de Canadá hasta Sudamérica. Se incluye la altitud, tipo de vegetación, época de flotación, nombres comunes y uso. Algunas especies como *P. pubescens* y *P. cordata* se han establecido en los trópicos del Viejo Mundo.

Palabras clave: sistemática, *Physalis* sect. *Epeteiorhiza*.

### ABSTRACT

The genus *Physalis* includes about 90 species which are tentatively grouped into four subgenera. Morphology is used to revise sect. *Epeteiorhiza*, subgenus *Rydbergis*. The species in this section are defined by their herbaceous habit, either glabrous or with vestiture of simple or glandular hairs, solitary flowers, with rotate yellow corollas and terete to strongly 5-angled fruiting calyces. Fourteen species ranging from Canada to South America are recognized by this study. Data of their altitudinal distribution, vegetation type, flowering, common names and uses are included. Some species, such as *P. pubescens* and *P. cordata* have become established in the Old World tropics.

Key words: systematics, *Physalis* sect. *Epeteiorhiza*.

## INTRODUCTION

The genus *Physalis*, with about 90 species, is among the largest genera in subfamily Solanoideae, surpassed only by *Lycianthes* and *Solanum*. Estimation of the number of species within the genus vary enormously, from 75 (D'Arcy, 1991) to 120 (Hendrych, 1989) probably because the species are similar morphologically, and collections with good field notes, as well as experimental work, are lacking. In addition, most of the early type materials is either inaccessible or lost. To date, the only comprehensive work on the genus is still Waterfall's (1958, 1967). A revision of the genus *Physalis*, although needed, seems unlikely in the near future because of the problems previously mentioned, and its complicated nomenclature.

The genus is easily recognized by its accrescent fruiting calyx that envelops the berry. Other genera (*Chamaesaracha*, *Leucophysalis*, *Deprea*, *Larnax*) share this character but differ in corolla shape, habit, or details of the inflorescence (see Estrada and Martínez, in press, for a key to the genera). *Physalis* had been considered a cosmopolitan genus, but workers (D'Arcy, 1991; Nee, 1991) agree that the genus is native to America. Species collected in the Old World tropics are almost certainly post-Colombian introductions, with the exception of *P. alkekengi* which is the only native species to the Old World (D' Arcy, 1991; Nee, 1991). The center of diversity of *Physalis* is Mexico with over 70 species, most of them endemic. The United States and Central America also have several endemic species; a few also occur in South America.

Several species have been under cultivation for a long time. Some are grown for their juicy berries, such as *P. philadelphica* Lam., in Mexico known as "tomate verde" or "tomate de cáscara", *P. peruviana* L. ("uchuba") from the Andes, and *P. grisea* (Waterf.) M. Martínez from the Eastern United States (Nee, 1991). *Physalis alkekengi* L. ("Chinese lantern") is used as an ornamental and a medicinal.

The four species have been introduced and established elsewhere. Other species such as *P. chenopodiifolia* Lam., *P. coztomatl* Moc. et Sessé ex Dunal, and *P. pubescens* L. are gathered from their wild populations for edible fresh fruits or for medicinal purposes. However, most of the species have restricted habitats, and many are known only from the type material or from a few additional collections.

The delimitation of sect. *Epeteiorhiza* is based mostly on cladistic analysis of restriction enzymes fragments of chloroplast DNA, as well as hair morphology based on scanning electron microscopy (Martínez, 1993). The species treatment is based on gross morphology of herbarium specimens and field data.

## TAXONOMIC HISTORY

*Physalis* was established by Linnaeus in 1753 with nine species subdivided into two groups. G. Don (1837) named the sections proposed by Nees von Esenbeck (1831) applying *Physalodendron* to the woody species, *Eurostorrhiza* to the perennial, rhizomatous species, *Epeteiorhiza* to the annual species, and *Anomalae* to the species

with tubular corollas noting that they might belong to another genus. Dunal (1852) recognized only sect. *Eurostorrhiza* and sect. *Epeteiorhiza* referring the species of sect. *Anomalae* and sect. *Physalodendron* to the genus *Withania*. Rydberg (1896) did not recognize these infrageneric categories and established the sections *Physalis* (as *Euphysalis*), *Microphysalis*, and *Megista*, further subdividing sect. *Physalis* into seven species groups that were later raised by Menzel (1951) to the rank of sections (see Martínez, in press, for a discussion on the nomenclature of the subdivisions). The characters used to subdivide the genus since Linnaeus (1753) are habit (shrubby, annuals or perennials), flower arrangement (solitary or aggregated), morphology of the flower bud, shape of the fruiting calyx, and pubescence.

As currently circumscribed, *Physalis* includes *Quincula* and *Margaranthus* (Martínez, 1993; Axelius, 1995), but excludes *P. amphitrica* and *P. calidaria*, which were transferred to the new genus *Tzeltalia* (Estrada and Martínez, in press). The genus is considered by Martínez (in press) as divided into four subgenera (*Physalis*, *Physalodendron*, *Quincula*, and *Rydbergis*). *Rydbergis* includes the majority of species and is subdivided into nine sections defined by habit, pubescence, hair morphology, and fruiting calyces.

### GENERAL MORPHOLOGY OF THE GENUS PHYSALIS

**Habit.** Life form can be of three kinds: 1) annual (e.g., *P. missouriensis*); 2) rhizomatous perennial geophytes (e.g., *P. cinerascens*), and 3) shrubby or arborescent perennials (e.g., *P. coztomatl* and *P. arborescens*). In tropical regions, the annual habit is not always absolute, and some plants may continue to persist for extended periods or produce new growth from the aerial parts, appearing somewhat woody at the base. However, these plants usually do not survive for more than two years.

*Physalis* species are mostly erect, varying in size from a few centimeters up to 2 m high (e.g., *P. nicandroides*). Some species such as *P. hederifolia* are prostrate, and only two species, *P. gracilis* and *P. longicaulis*, have repent stems that root at the nodes. Plants can either branch profusely (*P. crassifolia*) or maintain a single stem, (*P. melanocystis*). Stems of *Physalis* are usually terete, but in some species they are angled, as in *P. angulata*.

The species of sect. *Epeteiorhiza* are annual or non-rhizomatous perennial herbs, with perenating ligneous stems. All the species are erect and have terete stems.

**Leaves.** The leaves of *Physalis* can be sessile or petiolate, and the base of the blade is frequently oblique. Blades have entire, toothed, or serrate margins, and the shape varies from reniform to ovate and from linear to lanceolate. Leaves are alternate, but frequently geminate, these of similar shape but unequal in size, the smaller leaves about half the size or less than the larger. The size and shape of leaves show considerable infra-specific variation. Ordinary epidermal cells are polygonal in outline and lack surface sculpturing (Fig. 1a). Bessim and Guyot (1979) studied

stomatal characters of 56 species in 45 genera of the Solanaceae. They found stomata to be informative at the tribal and genus levels. In *Physalis*, stomata are confined to the lower leaf surface and are described as meso-perigenous anisocytic; a few perigenous anomocytic stomata are also present, a feature common to all species in the family (Bessis and Guyot, 1979). Neither the ordinary epidermal cells nor the stomata provide useful information at the specific level.

In sect. *Epeteiorhiza*, leaves are petiolated, with an elliptic, oblong, ovate, rhombic or deltate shape. Leaves are always alternate when mature, but at the top of the stem they are geminate.

*Vestiture.* Morphological differences in hair types proved diagnostic. Hairs have been used in several taxonomic studies in the Solanaceae, especially in *Solanum* (Seithe, 1979; Seithe and Anderson, 1982), where they have been useful at the level of series and species. In *Physalis*, hairs were used, along with other characters to group species (Rydberg, 1896). For example, species with branching hairs made up his *Stellatae* group. Seithe and Sullivan (1990) investigated the hair morphology of ten species of *Physalis*. They found two classes of hairs: 1) long, branched and unbranched hairs with or without glandular tips (Figs. 1 a, b); and 2) short hairs tipped with multicellular glands (Fig. 1 a). Both types of hairs developed from one epidermal cell. No variability was found in the second hair class, but the first was further subdivided into six types: gland-tipped unbranched, glandless unbranched, gland-tipped branched, glandless branched, stelliform, and dendroid-stelliform. Hairs on other organs of the plant were similar to those of the upper leaf surface and frequently, two or more kinds of hairs are intermixed.

When analyzed with the scanning electron microscope (SEM), *Physalis* presented two different hair surfaces: smooth and rugose (nomenclature of Barthlott, 1990). For example, members of section *Stellatae* (*P. cinerascens* and *P. pumila*) had branching hairs with a rugose secondary surface that contrasted with the smooth surface of the short multicellular glandular hairs (type-2, Fig. 1a).

Simple glandular hairs with a smooth surface were found in ten of the 14 species of section *Epeteiorhiza* (Fig. 1b). Only *Physalis minuta*, *P. cordata* and *P. grisea* have simple hairs that lack glands. Except for *P. porrecta*, which was glabrous, members of section *Epeteiorhiza* had short multicellular glandular hairs (type 2 of Seithe and Sullivan, Fig. 1a). However, simple multicellular glandular hairs were also present in members of other sections, e.g., *P. greenmanii* and *P. coztomatl* of section *Coztomatae*, and *P. lagascae* of section *Angulatae*.

*Flowers.* They are axillary and solitary except in *P. arborescens*, *P. melanocystis*, *P. aggregata* and *P. carpentieri*, where the flowers are aggregated into fascicles of two to five flowers. Flowers are usually pendulous, although a few species have flowers with a lateral orientation. Erect flowers are absent in the genus. In sect. *Epeteiorhiza*, the flowers are pedicellate, pendulous, and solitary in the leaf axis.

Corolla shape is usually rotate to campanulate (Fig. 2 a), either apically 5-angled, or 5-lobed (as in *P. alkekengi*). Tubular corollas with an open limb are rare, occurring

only in *P. glutinosa* and *P. campanula*. Urceolate corollas are present only in *P. solanaceous* (Fig. 2 b), whereas all members of sect. *Epeteiorhiza* have rotate corollas.

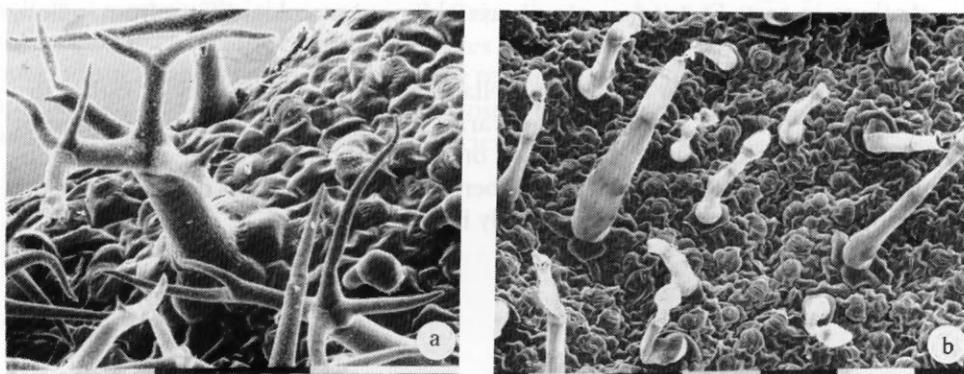

Fig. 1. Hair morphology of *Physalis*; a) long hairs (branching) and short hairs (glandular) from the abaxial surface of the leaves of *P. cinerascens* (A. Salinas F3917, TEX); b) long hairs, glandular, from the leaves of *P. ignota* (Britton and Wilson 5767, NY). Barr equals 0.1 mm.

Corolla color in most species varies from yellow to greenish or whitish, either maculated or not. Only *P. solanaceous* has purple corollas, whereas *P. alkekengi* has white corollas. Maculae can be a single, solid blotch (Fig. 2 c), or composed of several aggregated smaller dots (Fig. 2 d). The color of maculations varies from greenish, dull brown to dark blue or purple; the apex varies from obtuse to acute or acuminate (Fig. 2 c, d). The vast majority of species in *Physalis* have a mat of white hairs in the throat of the corolla, near the maculations. Sullivan (1986) suggested that such pubescence retains nectar which is produced in microquantities. Because most species of *Physalis* are bee pollinated (Sullivan, 1986), corolla color in the ultraviolet range can be distinctive. Sullivan (1986) studied the ultra violet light patterns of *P. cinerascens*, a dark-maculated species. She deduced that the yellow limb of the corolla is seen by the bee as yellow-orange, the throat maculations as black, hairs, anthers, pollen as white-yellow, and the veins as luminescent-white. Color and shape of the maculations show little variation within species, making them very useful characters.

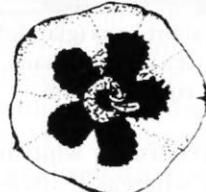

In sect. *Epeteiorhiza*, petals are yellow, cream yellow or whitish, either immaculated or with maculations. The color of the maculation can be greenish or light brown, therefore only slightly contrasting from the rest of the corolla, or strongly contrasting as dark blue or purple. All the maculations are solid, either confluent at the base, or separated.

Anthers in *Physalis* dehisce longitudinally and are basifixed. Color of anthers and filaments varies from green to yellow to blue-tinged, blue or purple. The color is taxonomically provisionally useful, because some intraspecific variation occurs. In *P. philadelphica* the anthers twist after dehiscence, in all other species the anther remain straight. Anther shape varies from sagittate, oblong or linear. The flowers

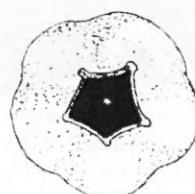

usually have one mature stamen when they first unfold; the remainder matures over several days. Pollen is shed over a 1-3 day period with one or more anthers shedding each day (Sullivan, 1986).

Anthers in sect. *Epeteiorhiza* are always oblong, but color differs from yellow, green, yellow with blue lines, or blue.

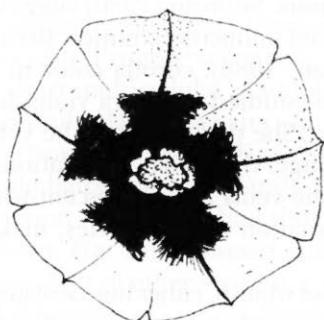

*Fruits.* The fruit of *Physalis* is a two-carpellate berry with either juicy or rather dry pericarp. The color of mature berries varies from green to yellow to orange or purple. Berries are sometimes produced on a gynophore. Seeds are usually abundant (*ca.* 50 seeds per fruit), but the number of seeds within fruits diminishes as the flowering season progresses, often to only five or six.

d

Fig. 2. Corolla shape and maculations in *Physalis*: a) rotate corolla of *P. pubescens* L.; b) urceolate corolla of *P. solanaceus* (Schltdl.) Axelius; c) solid maculation with obtuse apex of *P. gracilis* Miers; d) aggregated dots with acuminate apex of *P. coztomatl* Moc. et Sessé ex Dunal.

The berry is loosely enclosed by the accrescent, bladder-like calyx (Fig. 5). The shape of the fruiting calyx can be either strongly 5-angled (Fig. 3 a) or 10-angled = "terete" (Fig. 3 b). Fresh fruiting calyces are usually green, turning light brown or yellow at maturity (bright orange in *P. alkekengi*, almost black in *P. arborescens* and *P. melanocystis*). The shape of fruiting calyces has been used to subdivide the genus, but cladistic analysis based on chloroplast DNA indicates that some 5-angled fruiting species like *P. pubescens* may be more closely related to terete fruiting species (*P. missouriensis*) than to other 5-angled species as *P. pruinosa* (Martínez, 1993).

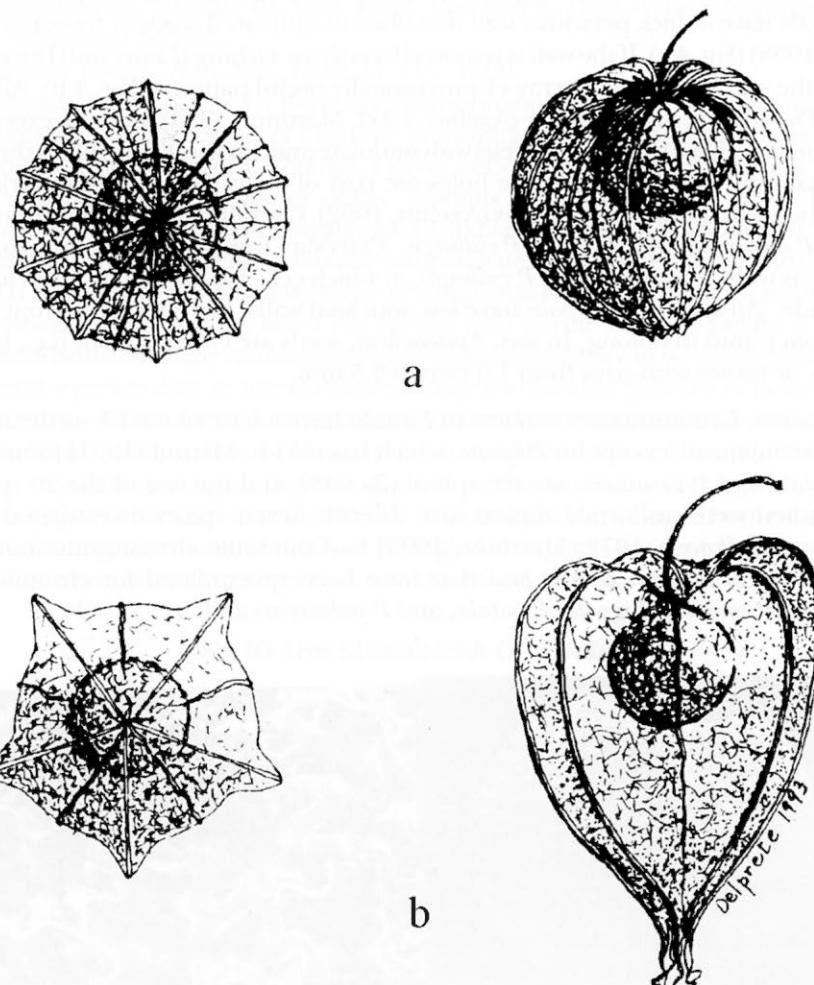

Fig.3. Accrescent calyx in *Physalis* in frontal and lateral view, respectively: a) terete calyx of *P. gracilis* Miers; b) 5-angled calyx of *P. cordata* Mill.

Most members of sect. *Epeteiorhiza* have invaginated, strongly 5-angled fruiting calyces. Only *P. leptophylla* and *P. missouriensis* have slightly 5-angled to almost terete calyces, which are only slightly invaginated.

**Seeds.** Seed morphology has been used to subdivide the family Solanaceae into subfamilies, it has been used to a limited extent at lower taxonomic levels (Bahadur and Farooqui, 1986). Seeds in *Physalis* vary in color from light yellow to brown, except for *P. parvianthera* that has black seeds. They vary in size from 0.6-3.0 mm in length. All species have reniform seeds, except for the oblique-triangular seeds of *P. parvianthera*. The seeds have a thick periclinal wall described in untreated seeds as foveolate (Waterfall, 1958) (Fig. 4 a). If the wall is removed by enzyme etching (Lester and Durrants, 1984), the seeds display an array of provisionally useful patterns (Fig. 4 b). All species of *Physalis* investigated so far (Axelius, 1992, Martínez, 1993), with the exception of *P. peruviana*, have shallow testa cells with undulate anticinal walls and holes through the thickening at the bottom. The holes are part of a layer of a tube-network that occurs beneath the outer epidermis (Axelius, 1992). Overall cell size varies from 0.07 mm in *P. carpentieri* to 0.2 mm in *P. rydbergii*. Cells vary from as long as wide, to twice as long as wide, excepting only *P. rydbergii*, in which cells are up to four times longer than wide. All species of *Physalis* have low anticinal walls, of which the bottom holes vary from round to oblong. In sect. *Epeteiorhiza*, seeds are either golden (i.e., bright yellow), or brown with sizes from 1.5 mm to 2.5 mm.

**Chromosomes.** Chromosome numbers in *Physalis* have a base of  $x=12$ , as the rest of the tribe Solaneae, except for *P. lobata*, which has  $n=11$ . Menzel (1951) found that *P. angulata* and *P. peruviana* are tetraploid ( $2n=48$ ), and the rest of the 20 species she studied were uniformly diploid with  $2n=24$ . Seven species investigated later (Averett and Powell, 1972; Martínez, 1993) had the same chromosome number. The members of sect. *Epeteiorhiza* that have been investigated for chromosome numbers (*P. cordata*, *P. ignota*, *P. patula*, and *P. pubescens*) all have  $2n=24$ .

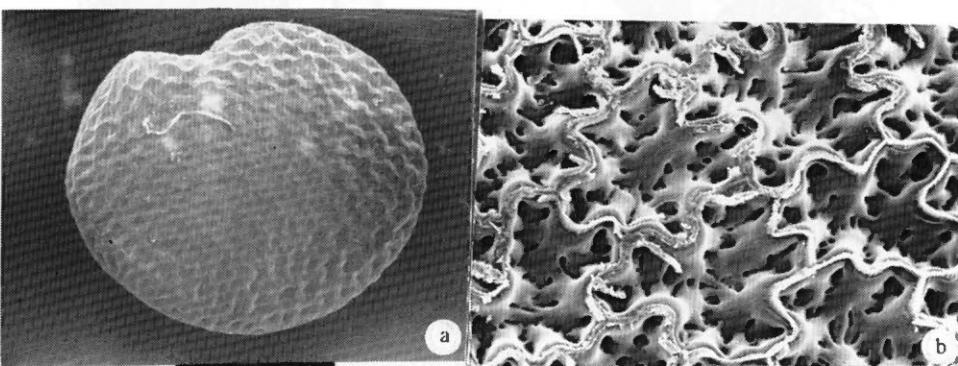

Fig. 4. Seeds of *Physalis*: a) untreated seed of *P. nicandroides* Schlechl. (L. Hernández 2488, TEX), bar equals 1 mm; b) same seed after treatment, bar equals 0.1 mm.

*Margaranthus* Schltdl., In. Sem. Hort. Halensis 8. 1838.-Type *Margaranthus solanaceus* Schltdl.

*Megista* Tourn., Ann. Soc. Linn. 17:115. 1869.

Annual or perennial herbs, forming rhizomes in some species, less frequently shrubs; vestiture composed of vesicles, or of simple, branching or glandular trichomes, frequently a mixture of two types of trichomes. Leaves petiolate, alternate, frequently paired; blades linear, oblong, elliptic or ovate, margins entire, toothed or lobed. Flowers pedicellate, solitary, or seldomly aggregated in axillary fascicles of 3-5 flowers; flowering calyces campanulate or seldom tubular-campanulate, 5-lobed; flowering buds plicate; corollas subrotate to campanulate-rotate or campanulate, seldom tubular-campanulate or urceolate, mostly yellow, but a few species with purple or white petals, if yellow, maculated with 5 strongly contrasting or dull maculations that can be solid or composed of several separate dots, or maculations wanting; corolla tube glabrous or pubescent at the insertion of filaments; filaments filiform or flattened; stamens 5, anthers dehiscing longitudinally, oblong, linear-oblong or sagittate, green, yellow, blue, blue-tinged or purple; style filiform, stigma capitate, truncate or clavate. Fruit a berry, green, purple, orange, yellow or brown at maturity, loosely and completely enveloped by the accrescent calyces; fruiting calyces reticulate, 5- or 10-angled, invaginated at the base or not; seeds several to many, laterally compressed, testa foveolate, seldom tuberculate.

## KEY TO THE SUBGENERA OF PHYSALIS

1. Corolla lobed
  2. Corolla rotate, distinctly lobed, immaculate, pollen microspinulate, fruit a thin walled berry, chromosomes  $x = 12$ , one with a conspicuous satellite, plants herbaceous, native to the Old World. .... Subgen. *Physalis*
  2. Corolla rotate, distinctly lobbed, maculated, pollen granular, fruit a thick walled juicy berry, chromosomes without a conspicuous satellite, plants distinctly ligneous, native to the New World. .... Subgen. *Physalodendron*
1. Corolla not lobed.
  3. Corolla rotate, purple, immaculate, pollen microspinulate, fruit a dry berry, chromosomes  $x = 11$ , plants native to the deserts of North America. .... Subgen. *Quincula*
  3. Corolla rotate, campanulate or urceolate but not distinctly lobed, mostly maculated, pollen granular, fruit a thick walled berry, chromosomes  $x = 12$  without a satellite, plants native to the New World. .... Subgen. *Rydbergis*

## KEY TO THE SECTIONS OF SUBGENUS RYDBERGIS

1. Flowers aggregated into fascicles, corky bodies among the seeds. .... Sect. *Carpenteriae*
1. Flowers solitary, fruits without corky bodies among the seeds.
  2. Corolla maculations composed mostly of separated spots, plants mostly of high elevations (>1,500 m). .... Sect. *Coztomatae*
  2. Corolla maculations solid, plants mostly of lower elevations.
    3. Corolla tubular campanulate. .... Sect. *Campanulatae*
    3. Corolla mostly rotate, seldom urceolate, never tubular campanulate.
      4. Plants perennial through rhizomes, with simple or branching hairs.
        5. Plants mostly covered with branching hairs. .... Sect. *Stellatae*
        5. Plants mostly covered with simple hairs, or a few branching hairs present.
          6. Plants covered with simple hairs with a smooth surface, hairs not aggregated. .... Sect. *Lanceolatae*
          6. Plants covered with hairs aggregated into tufts, or hairs with a rugose surface.
            7. Plants with hairs in tufts, corolla immaculate, restricted to Tehuacán. .... Sect. *Tehuacanensis*
            7. Plants with solitary hairs, corolla maculated, plants restricted to other dry areas of Mexico. .... Sect. *Rybergis*
        4. Plants annual or perennial through a ligneous base, seldomly forming rhizomes, but if so, then the plants glabrous
          8. Fruiting calyces terete, plants glabrous or with simple hairs. .... Sect. *Angulatae*
          8. Fruiting calyces mostly 5-angled, if almost terete, then the plants densely pubescent. .... Sect. *Epeteiorhiza*

*Physalis* subg. *Rybergis* Hendrych, *Acta Univ. Carol.-Biol.* 33:1-42. 1989. Sect.

*Epeteiorhiza* G. Don, Gen. Syst. IV:449. 1837. Lectotype: *Physalis pubescens* L.

*Physalis* sp. group *Pubescentes* Rydb., Mem. Torrey Bot. Club 4:332. 1896.

*Physalis* sp. group *Leptophyllae* Rydb., Mem. Torrey Bot. Club 4:328. 1896.

Annual or perennial herbs, but if perennials, not forming rhizomes; vestiture commonly composed of simple or 1-4 celled glandular hairs or a mixture of both, the secondary surfaces smooth, glands dark brown or transparent. Leaves alternate and paired, one leaf always much smaller (less than one half) than the other, blades varying from oblong to lanceolate or ovate, base oblique, margin entire, undulate, dentate or crenate. Flowers pedicellate, solitary in the leaf axils; flowering calyces campanulate, the lobes deltoid, triangular, lanceolate or acuminate; corolla rotate-campanulate, yellow to greenish-cream, 0.3-2.0 cm in diameter; petals maculate with five strongly contrasting purple spots, or maculations dull brown or greenish, seldomly wanting; corolla tube glabrous or pubescent within at insertion of filaments; filaments flattened, blue, purple, or green; anthers oblong, yellow, green, blue-tinged or blue; style filiform, stigma capitate. Fruit a spherical or ellipsoid berry, glutinous or not, green, yellow or dark brown at maturity; fruiting calyces mostly 5-angled, seldom terete, invaginated basally or not; seeds golden or dark brown, more than 50 per fruit, testa foveolate.

The species of sect. *Epeteiorhiza* are native to America, ranging from southern Canada to Northern Argentina and the West Indies. The weedy *Physalis pubescens* has become established in the Old World, and *P. cordata* has been collected infrequently in China and India from open areas of lowland habitat. A few species are part of the native vegetation of oak or tropical montane forest.

#### KEY TO THE SPECIES OF SECT. EPETEIORHIZA

1. Mature stems glabrous to minutely puberulous
  2. Flowers 0.5-0.6 cm wide; flowering calyces with deltate lobes; fruiting calyces 1.5-2.0 cm long. .... *7. P. minuta*
  2. Flowers 0.8-2.0 cm wide; flowering calyces with lanceolate lobes; fruiting calyces 3.0-5.5 cm long.
    3. Flowering calyces villous, the lobes 2.5 mm wide; plants of high (> 1,500 m) elevations. .... *12. P. porrecta*
    3. Flowering calyces glabrous to minutely puberulous, the lobes 0.8-1.0 mm wide; plants of low elevations. .... *2. P. cordata*
1. Mature stems villous, velutinous, sericeous or tomentose.
  4. Calyx lobes deltate; fruiting calyces 10-angled, not invaginated at the base.
    5. Petals with 5 purple maculations. .... *6. P. leptophylla*
    5. Petals immaculate. .... *8. P. missouriensis*
  4. Calyx lobes narrowly triangular, lanceolate or acuminate; fruiting calyces strongly 5-angled, invaginated at the base.
    6. Petals with strongly contrasting purple or dark blue maculations; fruiting calyces 1.5-2.0 (3.0) cm wide.
      7. Fruiting calyces 1.5 cm wide or less, plants restricted to Chiapas and Guatemala. .... *1. P. angustiphysa*
      7. Fruiting calyces 2.0 cm wide or more.
        8. Fruiting calyces deeply invaginated; corolla maculations not merging at the base.
          9. Leaf margins dentate; plants of north and central Mexico
            - ..... *11. P. patula*
          9. Leaf margins crenate; plants restricted to the Rocky Mountains, USA
            - ..... *9. P. neomexicana*
        8. Fruiting calyces not deeply invaginated; corolla maculations merging at the base.
          10. Pubescence without glandular hairs; anthers yellow; plants odorless or nearly so. .... *3. P. grisea*
          10. Pubescence glandular; anthers mostly blue or purple; plants with strong odor. .... *14. P. pubescens*
      6. Petals with weakly contrasting greenish or brown maculations, or maculations absent; fruiting calyces (2.5) 3-4.5 cm wide.
        11. Fruiting calyces tomentose throughout, hairs not glandular. .... *4. P. ignota*
        11. Fruiting calyces glandular-pubescent at least on the veins.
          12. Fruiting calyces 1.5-3.0 cm long. .... *11. P. patula*
          12. Fruiting calyces 3.0-5.5 cm long.

13. Fruiting pedicel much thickened, 1.1-2.0 mm in diameter..... *10. P. nicandroides*  
 13. Fruiting pedicel not thickened, 0.5 mm in diameter.  
   14. Anthers yellow, fruit glutinous..... *13. P. pruinosa*  
   14. Anthers blue or blue-tinged, fruit not glutinous ..... *5. P. latiphypha*

**1. *Physalis angustiphypha*** Waterf., Rhodora 69:228. 1967. Type: Guatemala: Huehuetenango, La Sierra (Tujimach) across river from San Juan Atitlán, 8 Sep 1952, Steyermark 51977 (Holotype: US!; Isotype: F!)

Perennial herbs 20-100 cm high. Stems densely villous with multicellular glandular hairs up to 2 mm long. Leaves villous, 5-14 cm long; petioles 1.5-5.0 cm long, blades ovate to deltate, densely villous throughout, 3-10 cm long, 3.5-7.0 cm wide, apex acute, base cordate, margin coarsely dentate to almost entire. Flowering peduncles 4.5-9.0 mm long; flowering calyces villous with triangular lobes 2.5-3.5 mm long, 1.5-2.0 mm wide; corollas yellow, 1.1-1.5 cm in diameter, the petals with 5 separate strongly contrasting maculations, pubescent within; filaments and anthers blue or blue-tinged, anthers 2.5-2.8 mm long. Fruiting peduncles 4.5-9.0 mm long; fruiting calyces 5-angled, 2-3 cm long, ca. 1.5 cm wide, villous throughout. Mature berry spherical, ca. 1.5 cm in diameter, containing numerous golden foveolate seeds ca. 2 mm in diameter.

**Distribution** (Fig. 5). Restricted to Mexico and Guatemala, 800-2900 m in oak or tropical montane forest.

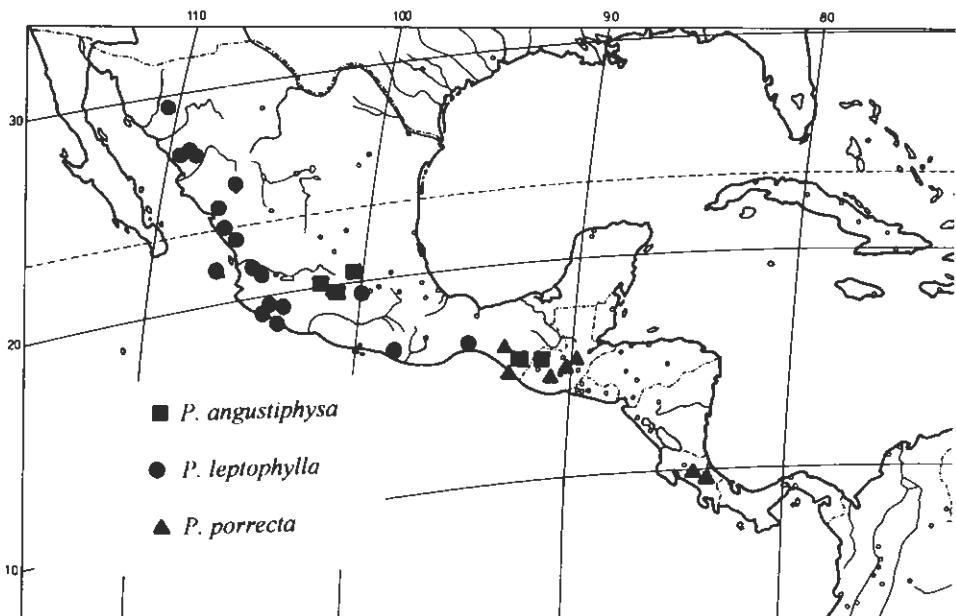

Fig. 5. Distribution of *P. angustiphypha*, *P. leptophylla*, and *P. porrecta*.

**Flowering.** July-January.

**Common names.** "Chush-gutz", "tomate-zope" (Guatemala), "chichol-antivo" (tzotzil), "miltomate" (Mexico).

**Uses.** Reported as medicinal from Chiapas.

**Observations.** *Physalis angustiphylla* seems to be closely related to *P. pubescens* L., from which it is readily distinguished by its perennial habit, very narrow fruiting calyces (not exceeding 1.5 cm wide), and a very dense vestiture.

**Representative specimens examined.** GUATEMALA HUEHUETENANGO: between Puente Negro and Los Alisos on way to Aguacatán, 16 Sep 1971, Molina 26548 (F). MEXICO: CHIAPAS: Mpio. Ocozocoautla de Espinosa, head of the Río de la Venta at Chorreadero near Derna, 24 Aug 1974, Breedlove 36559 (CAS, MEXU, NY). GUANAJUATO: 4 km al E de Tierras Negras, municipio de Pénjamo, 17 Nov 1991, J. Rzedowski 51282 (IEB, QMEX). MICHOACÁN: Zitácuaro-Coyota, 25 Aug 1938, Hinton 13156 (F, NY, US); Cerro La Alberca, municipio de Villa Jiménez, 20 Nov 1991, E. Pérez y E. García 2590 (IEB, QMEX); 5 km al N de Atécuaro, municipio de Morelia, 21 Jul 1992, J. Rzedowski 51555 (IEB, QMEX).

2. *Physalis cordata* Mill., Gard. Dict. 8:14. 1768. Type: Mexico: Veracruz, without further locality, 1730, *Houstoun* s.n. Holotype: BM, Sloane collection. Photoholotype BH!

*Physalis clarionensis* Waterf., Rhodora 69:326. 1967. Type: Mexico: Colima: Clarion Island, Mar-Jun 1897, Anthony 411. Holotype: UC. Isotypes: CAS! NY!

*Physalis galapagoensis* Waterf., Rhodora 70:408. 1968. Type: Ecuador: Galapagos Islands, Isla Santa Cruz, vicinity of Charles Darwin Research Station, Academy Bay, 15 Feb 1964, Wiggins 18724. Holotype: DS. Isotype: OKL. Neither the holotype nor the isotype has been located; however, examination of the 13 additional collections cited by Waterfall leaves little doubt as to the taxon concerned, and its name relegated to synonymy herein.

Annual herb 25-200 cm high. Stems glabrous to minutely puberulous. Leaves glabrous, 5-20 cm long; petioles 2.5-6.0 cm long; blades ovate to deltate, glabrous or sometimes puberulent, 3.5-11.0 cm long, 3-8 cm wide, apex acute to acuminate, base cordate, sometimes oblique only up to 5 mm off, margins dentate to almost entire. Flowering peduncles 3.5-8.0 mm long; flowering calyces glabrous to puberulent, with lanceolate lobes, 2-5 mm long, 0.8-1.0 mm wide; corollas yellow, 0.8-2.0 cm in diameter, petals with 5 dark brown to purple maculations, pubescent within; filaments brown, anthers yellow, blue-tinged or blue, up to 3 mm long. Fruiting peduncles 1.5-2.4 cm long; fruiting calyces strongly 5-angled, 3.0-4.5 cm long, 1.2-3.0 cm wide, always longer than wider, glabrous throughout to minutely puberulous. Mature berry ellipsoid, ca. 1.5 cm long, 1.0 cm wide, yellow, containing numerous brown foveolate seeds ca. 1.5 mm in diameter.

**Distribution** (Figs. 6, 7). From southern USA and throughout the Mexican and Central American lowlands to Brazil in South America and the West Indies. Introduced to Asia. The plant is a weed of lowland habitats, mostly occurring from 0 to 100 m, in sandy or clay soils. In the greenhouse, the species is selfing and very sensitive to drought.

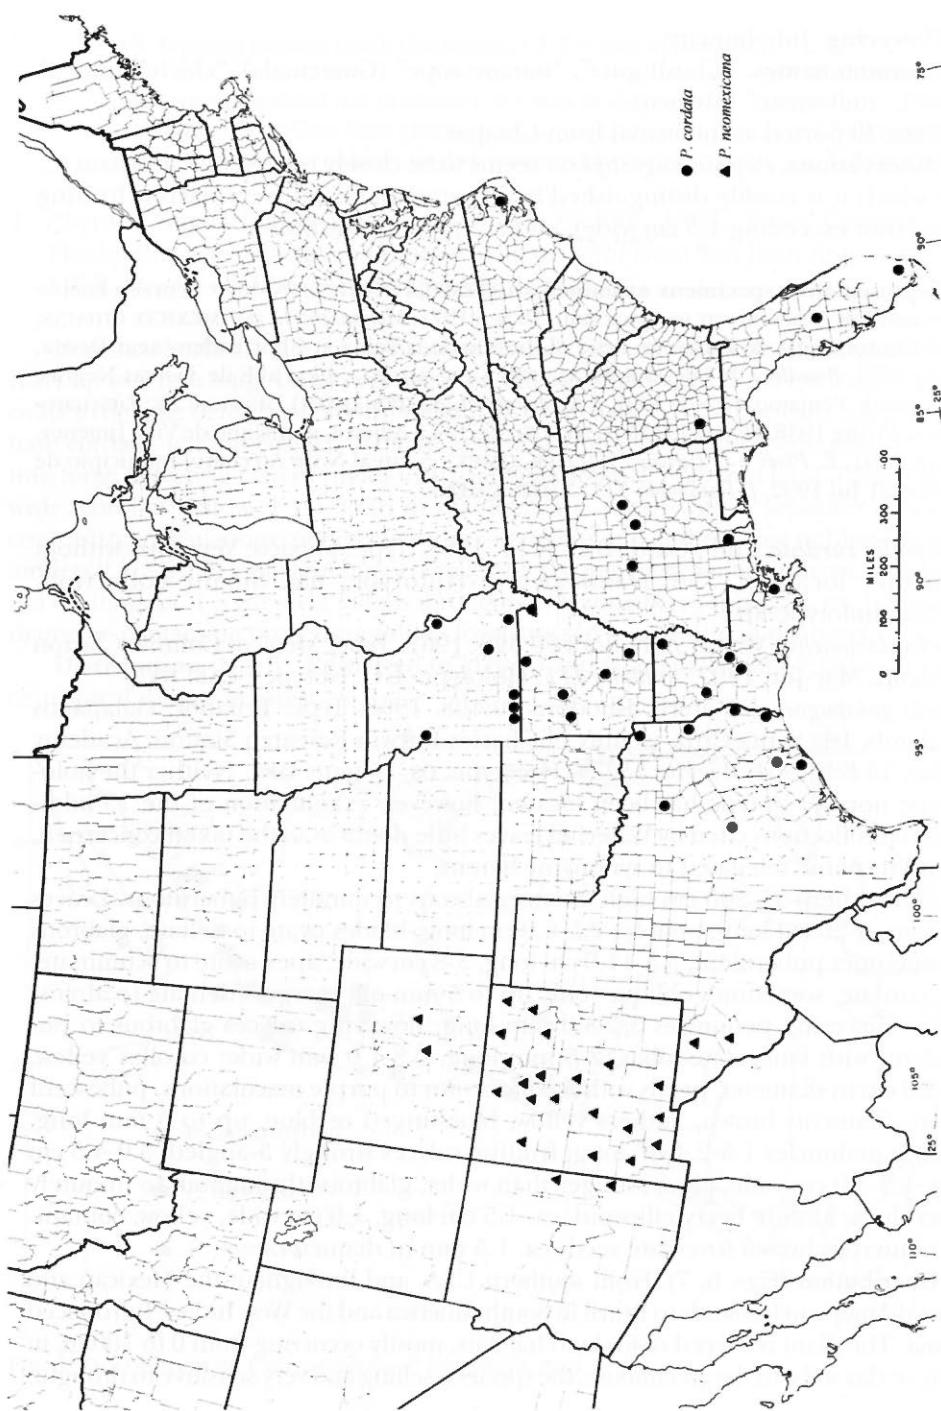

Fig. 6. Distribution of *P. cordata* in the United States and *P. neomexicana*.

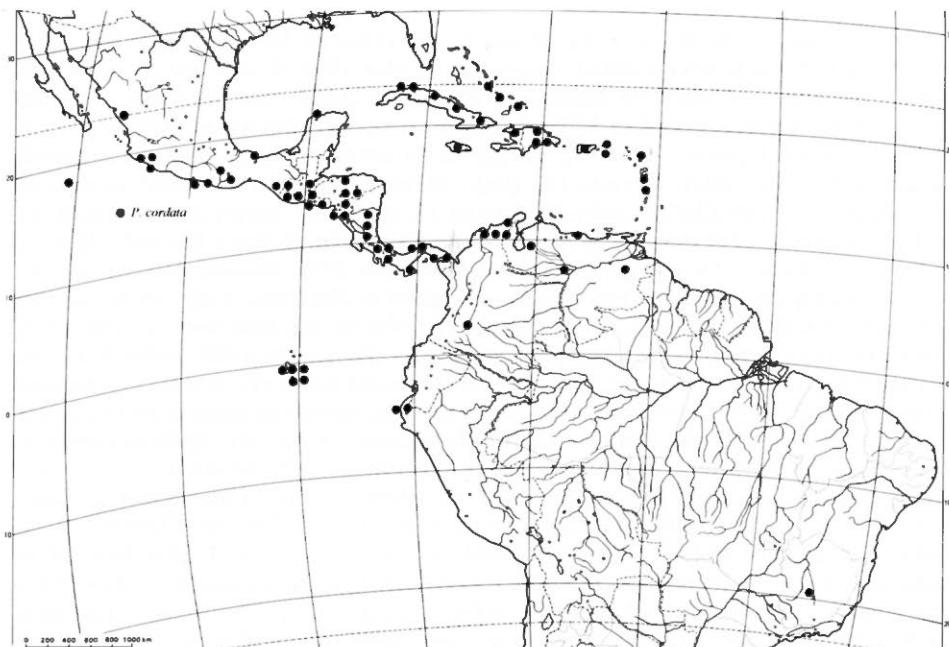

Fig. 7. Distribution of *P. cordata* in Mexico, Central America, South America and the West Indies

**Flowering.** In the USA flowering from July to November. In the rest of its range flowering throughout the year.

**Common names.** "Joapoca" (Brazil); "trepotoropo" (Colombia); "huevito", "huevo de tortuga", "miltomate" (El Salvador); "tomatillo" (Guatemala); "chimbomba menuda" (Nicaragua); "ground cherry" (USA).

**Observations.** *Physalis cordata* is probably dispersed by water, which perhaps explains its presence in the Galapagos and Clarion islands. *Physalis clarionensis* is but a depauperated form of *P. cordata*, since both have been collected at the same locality. The species has been collected in China and India where the species is probably adventive.

**Representative specimens examined.** BAHAMAS: Caicos Islands, S Caicos, 14-16 Dec 1907, Wilson 7674 (F, NY). BERMUDA: Sandys Par., 18 Jul 1905, Moore 3443 (CAS). **3. *Physalis grisea* (Waterf.) M. Martínez, Taxon 42:103. 1993. *Physalis pubescens* L. var. *grisea* Waterf., Rhodora 60:167. 1958. Type: USA: Massachusetts, Middlesex Co., Cambridge, rubbish heap, 24 Sep 1884, Walter Deane s.n. Holotype: GH! Isotype: NY!**

Annual herbs 10-50 cm high. Stems sericeous, non glandular hairs multicellular, 0.5-3.0 mm long. Leaves mostly sericeous, orange-tinged when dry, 10-20 cm long; petioles 5-7 cm long; blades ovate to lanceolate, apex acute to acuminate, base oblique with a difference of 0.5-1.0 cm, margins coarsely dentate. Flowering peduncles 4-6 mm long; flowering calyces with triangular lobes 1.5-2.2 mm long, sericeous; corollas yellow 0.7-1.0 mm in diameter, the petals with 5 dark purple maculations, glabrous within; filaments purple, anthers yellow or sometimes with a faint tinge of blue, 1.1-2.0 mm long. Fruiting peduncles 6-10 mm long; fruiting calyces strongly 5-angled, 2.5-3.0 cm long, 1.0-2.2 cm wide, always longer than wider, sericeous throughout with multicellular hairs. Mature berry spherical, 1.0-1.5 cm in diameter, yellow, containing numerous brown foveolate seeds 1.5-2.0 mm in diameter.

**Distribution** (Fig. 8). From southern Canada throughout the USA. Some specimens are believed to represent introductions; the original natural range was probably the NE USA. The vast majority of collections were made well over 20 years ago, suggesting perhaps that the natural populations are becoming decimated. The plant grows spontaneously in disturbed habitats (cultivated fields and waste areas).

**Flowering.** From May to October.

**Common names.** "Hairy ground cherry", "husk tomato", "shuck tomato", "strawberry tomato", "dwarf cape-goosberry".

**Uses.** The sweet fruit is eaten fresh or in preserves. The species is commonly offered for sale in seed catalogs.

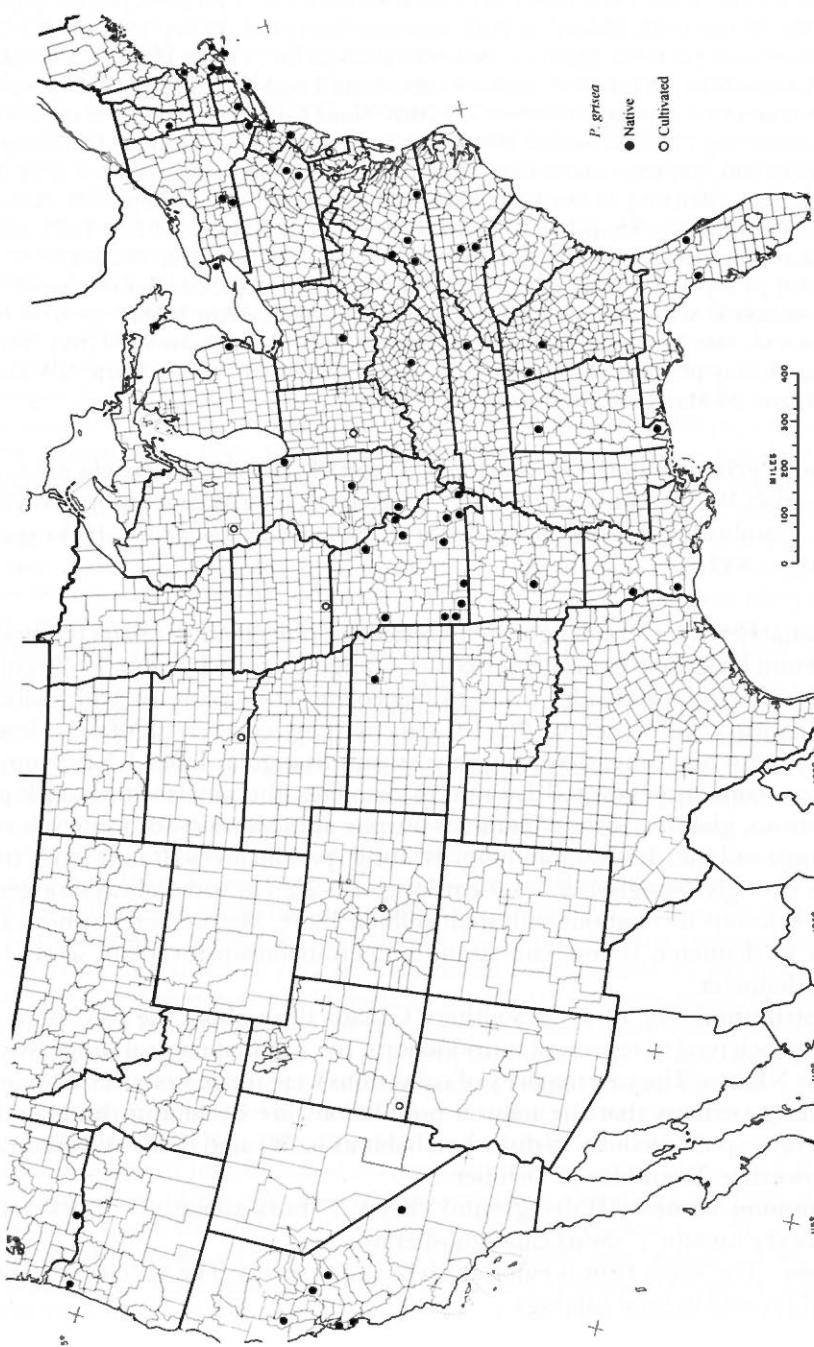

Fig. 8. Distribution of *P. grisea*.

**Observations.** *Physalis grisea* is closely related to *P. pubescens*, from which it is probably derived through human selection. The two are readily distinguished by the color of the anthers (yellow in *P. grisea*, mostly purple in *P. pubescens*), the coarsely dentate leaves, the sweet berry, and the lack of glands in the hairs. In living plants, *P. grisea* does not emit the strong odor of *P. pubescens*.

**4. *Physalis ignota*** Britton, Mem. Torrey Bot. Club 16:100. 1920. Type: Cuba: Santa Clara, Rio Arimao, 22 Mar 1910, *Britton & Wilson* 5767. Holotype: NY!

***Physalis pentagona*** S.F. Blake, Contr. U.S. Natl. Herb. 24:20. 1922. Type: Guatemala: Izabal, Los Amates, 9 May 1919, *Blake* 7313. Holotype: US!

Annual herbs, 30-500 cm high, densely covered with short multicellular glandular grey hairs throughout. Leaves tomentose, 7-19 cm long; petioles 1.5-8.0 cm long; blades mostly elliptic (rarely ovate), 5.5-11.5 cm long, 3-9 cm wide, apex acuminate, base oblique (rarely cordate), margin entire to rarely dentate. Flowering peduncles 3.5-6.0 mm long; flowering calyces with triangular lobes, 2-3 mm long, 0.6-1.1 mm wide; corollas yellow or greenish-cream, 6-11 mm in diameter, immaculate, pubescent within; filaments green or purple, anthers green or blue-tinted, 1.6-2.5 mm long. Fruiting peduncles 10-17 mm long. Fruiting calyces strongly 5-angled, 2-5 cm long, 2-4 cm wide, tomentose throughout. Mature berry spherical, ca. 1 cm in diameter, containing numerous seeds ca. 1.5 mm in diameter.

**Distribution** (Fig. 9). From Chiapas (Mexico) throughout Central America and the West Indies. The plant occurs from sea level up to 1500 m in sandy soils, usually associated with rivers or streams. The species is sympatric with *P. pubescens* and *P. gracilis*.

**Flowering.** Throughout the year.

**Common names.** "Huevo de tortuga", "miltomate" (El Salvador); "soplón", "miltomate" (Guatemala); "tomatillo", "vejiga de perro", "farolito" (Honduras); "popa", "popita" (Nicaragua).

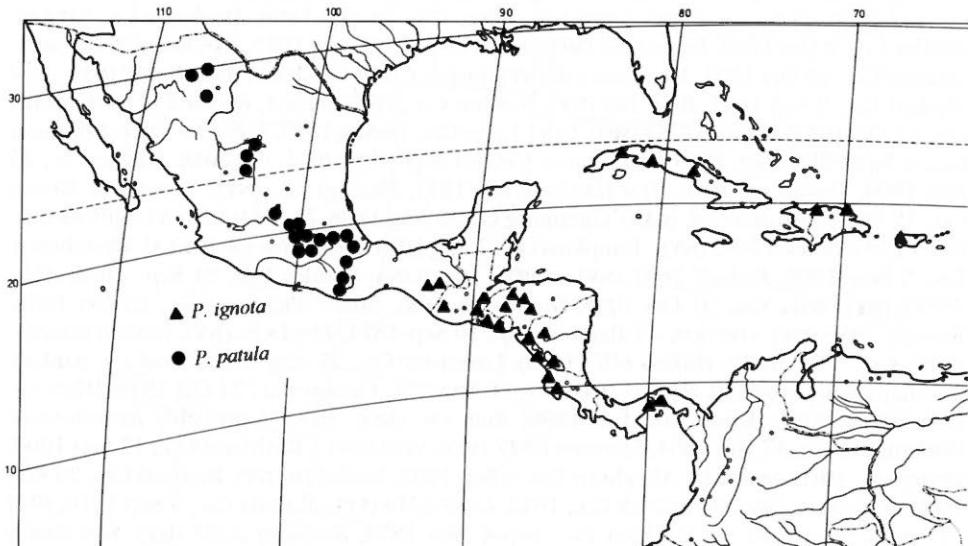

Fig. 9. Distribution of *P. ignota* and *P. patula*.

**Observations.** *Physalis ignota* is readily distinguished from the other species in the section by its very small corolla and large fruiting calyces which are densely tomentose. *Physalis ignota* is adapted to wet areas. Nevertheless, it is probably closely related to *P. pruinosa* and *P. nicandrodes*, both adapted to dry habitats, sharing with them the large, deeply invaginated fruiting calyces and the corollas without strongly contrasting maculations.

5. *Physalis latiphysa* Waterf., Rhodora 60:169. 1958. Type: USA: Arizona, Pima Co., Rondstadt Ranch east of Baboquivari Mountains, 23 Sep 1939, Kearney & Peebles 14425. Holotype: ARIZ!

Annual herbs 30-45 cm high. Stems densely glandular-pubescent, hairs multicellular. Leaves sericeous, 5.5-16.0 cm long; petioles 2.5-7.5 cm long; blades ovate, sericeous, 3.0-8.5 cm long, 1.5-7.0 cm wide, apex acuminate, base truncate, seldomly oblique up to 3 mm off, margin entire to seldomly dentate with up to 4 teeth per side. Flowering peduncles 4-11 mm long; flowering calyces glandular-pubescent with acuminate lobes, 2.2-2.5 mm long, 1.0-1.5 mm wide; corollas cream-yellow 3.5-4.0 mm in diameter, petals with 5 separate dark blue maculations within;

filaments pubescent, blue; anthers blue or blue-tinged, ca. 1 mm long. Fruiting peduncles 1.8-2.0 cm long; fruiting calyces strongly 5-angled, 3-4 cm long, 2.5-3.5 cm wide, frequently as long as wide, glandular-pubescent throughout. Mature berry spherical, 1.3-2.0 cm in diameter, not glutinous, containing numerous brown foveolate seeds ca. 2.5 mm in diameter.

**Distribution** (Fig. 10). From southern Arizona, known from only one collection in Sonora, Guanajuato and Michoacán (Mexico).

**Flowering.** July-September.

**Observations.** *Physalis latophysa* is closely related to *P. pruinosa* from which it differs in possessing shorter flowering pedicels and blue anthers. These characters place it also close to *P. nicandroides*, but *P. latophysa* has longer hairs, thinner fruiting peduncles, and papery (not leathery) fruiting clayces. From both, *P. latophysa* differs in having a non-glutinous fruit.

**Specimens examined.** MEXICO: GUANAJUATO: 4 km al N de Uriangato, municipio de Uriangato, 16 Oct 1992, J. Rzedowski 51820 (IEB, QMEX). MICHOACÁN: 7 km al E de Villa Jiménez, sobre el camino a Copándaro, 5 Oct 1986, J. Rzedowski 40745 (IEB, QMEX). SONORA: between Tepapa and Batuc, 28 Sep 1934, Wiggins 7503 (CAS). UNITED STATES OF AMERICA: ARIZONA: Cochise Co., 21 Aug 1981, Van Devender s.n. (ARIZ). Pirina Co., 31 Aug 1940, Kearney 14932 (ARIZ, US). Santa Cruz Co., 30 Aug 1931, Harrison 8158 (ARIZ).

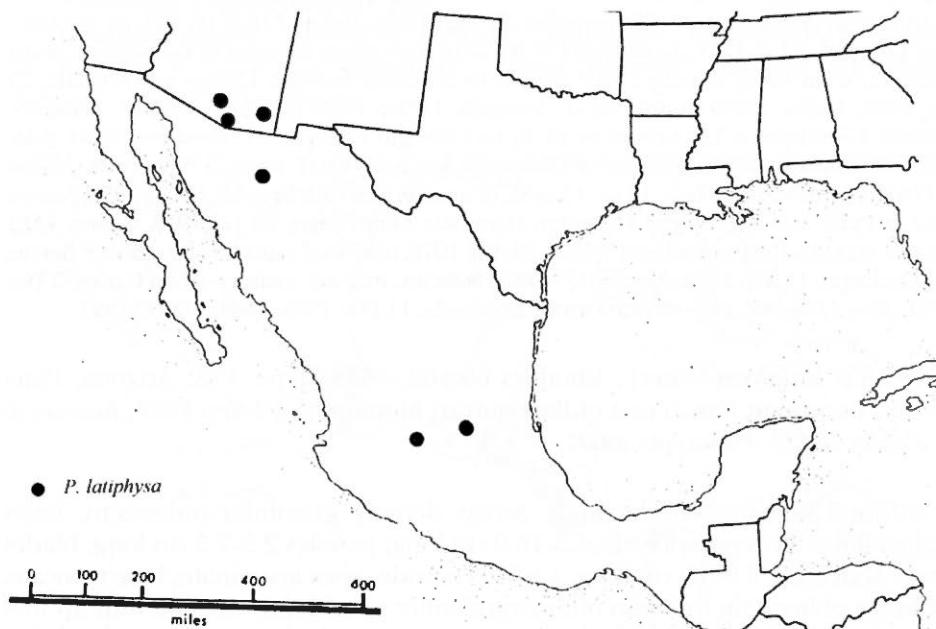

Fig. 10. Distribution of *P. latophysa*.

6. *Physalis leptophylla* B. L. Rob et Greenm., Proc. Amer. Acad. Arts 29:389. 1894. Type: Mexico, Sinaloa near Mazatlan, Jan 1889, W.G. Wright 1252. Lectotype: GH! (Fig. 11).

Annual herbs 15-100 cm high, profusely branched. Stems villous with multicellular glandular hairs up to 2 mm long. Leaves villous 7.5-15.0 cm long; blades ovate to elliptic, villous especially along the veins, 4-10 cm long, 2.5-6.0 cm wide, apex acuminate, base cordate, sometimes oblique up to 4 mm off, margin entire. Flowering peduncles 2.5-3.0 mm long; flowering calyces villous with deltate lobes 1.0-1.5 mm long, 1.0-1.5 mm wide; corollas pale yellow, 0.7-11.0 mm in diameter, the petals with 5 separate purple maculations, glabrous within; filaments brown; anthers blue or blue-tinged, rarely yellow, 1.5-2.0 mm long. Fruiting peduncles 2.5-3.0 mm long; fruiting calyces slightly 5-angled to terete, only slightly invaginated, 1.5-2.5 cm long, 0.9-1.8 cm wide, always longer than wide, villous throughout. Mature berry ca. 1 cm in diameter, containing numerous golden foveolate seeds ca. 1 mm in diameter.

**Distribution** (Fig. 5). Restricted to Mexico in the Pacific lowlands. The plant is a weed of dry habitats growing in disturbed habitats of tropical forest and scrubland, sea level to 600 m. Although not frequently collected, the plant is reported as abundant where encountered.

**Flowering.** Throughout the year.

**Common names.** "Tomate", "tomatillo", "tomate del monte", "shiquipiltzi".

**Uses.** The ripe fruits are cooked in Sonora.

**Observations.** *Physalis leptophylla* is sympatric with *P. pruinosa* and several mixed collections have been noted (i.e. Gentry 4771 NY, Lott 1455 F, MEXU, MO). The former is readily distinguished from the latter by the shape of the calyx lobes (obtuse in *P. leptophylla*, acuminate in *P. pruinosa*) and the length of the peduncles that in *P. leptophylla* never exceed 0.3 cm, whereas *P. pruinosa* has 1.7-3.0 cm long peduncles.

*Physalis leptophylla* is probably closest to *P. missouriensis* and *P. pubescens*. From the former species it differs in the presence of corolla maculations and leaf shape and from the latter it differs in the shape of calyx lobes (obtuse vs. triangular) and fruiting calyces (almost terete in *P. leptophylla*). Rydberg (1896) included this species in his series *Leptophyllae*, which I do not recognize as valid based on cpDNA and epidermal SEM evidence (Martínez, 1993).

**Representative specimens examined:** MEXICO: COLIMA: Vicinity of Manzanillo, 2 Dec 1925, Ferris 6134 (CAS). DURANGO: 10 mi N of Tamazula, 18 Dec 1939, Gentry 5270 (CAS, NY). Elota, 5.7 mi N of jct with road to La Cruz on México 15, 28 Jan 1962, Breedlove 1549 (CAS). SONORA: Alamos, 28 Oct 1939, Gentry 4771 (CAS, F, NY, US).

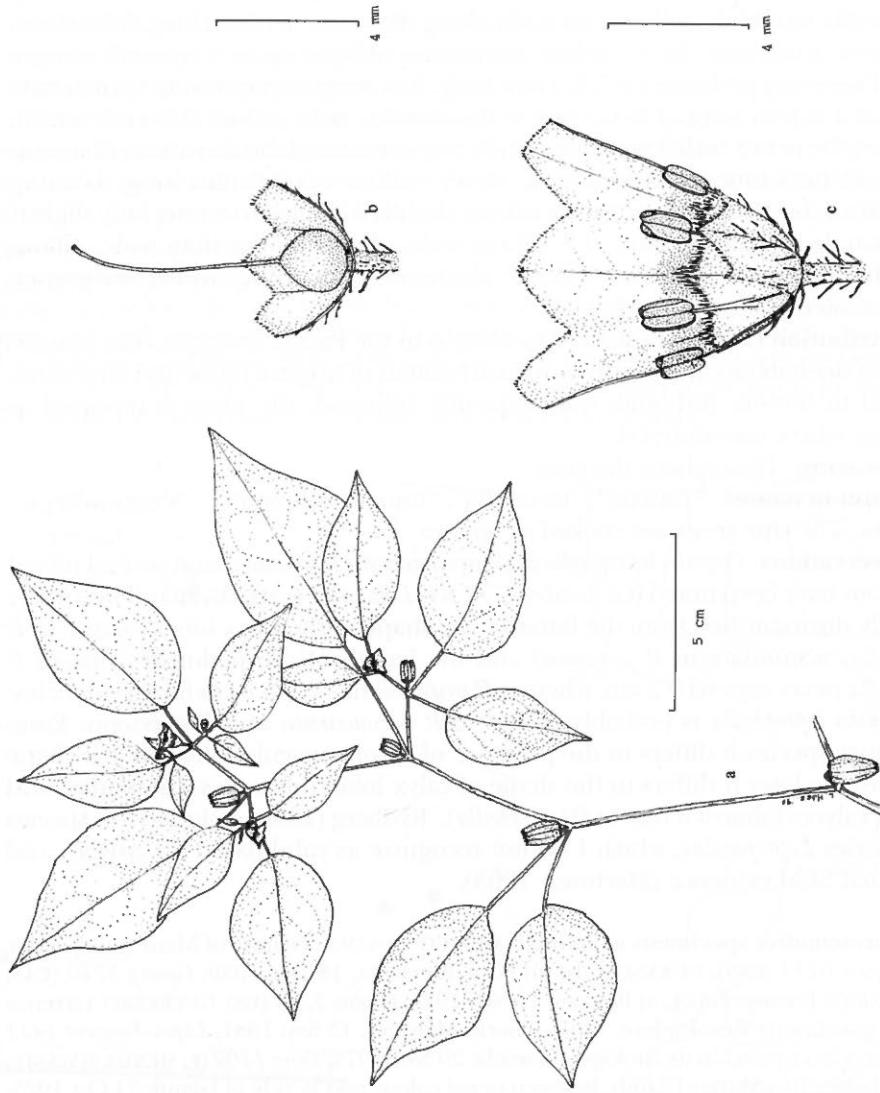

Fig. 11. *P. leptocephylla* B. L. Rob et Greenm.: a) branch with flowers and fruits; b) detail of the ovary and style; c) detail of the corolla.

**7. *Physalis minuta*** Griggs, Torreya 3:138. 1903. Type: Mexico: Guerrero, Acapulco, winter of 1894-1895, *Palmer* 304. Holotype: US! A voucher with the same collection number is on deposit at NY!, but the plant is a specimen of *P. philadelphica*.

*Physalis mimulus* Waterf., Rhodora 69:211. 1967. Type: Mexico: Colima, Socorro Island, Mar 1889, *Townsend* s.n. Holotype: US!

Annual herbs 15-40 cm high. Stems strigose, becoming glabrate with age. Leaves strigose, 3.5-9.9 cm long; petioles 2.0-5.5 cm long, blades lanceolate, ovate to broadly ovate, becoming glabrate with age, 1.5-4.0 cm long, 0.5-2.5 cm wide, the apices acute, bases obtuse, oblique up to 5 mm off, margins entire to undulate. Flowering peduncles 3.5-5.5 mm long, flowering calyces strigose with deltate lobes 1.0-1.5 mm long, 0.5-1.0 mm wide; corollas yellow, 5-6 mm in diameter, petals immaculate or with 5 separate purple maculations, glabrous within; filaments purple, anthers yellow, 1.0-1.5 mm long. Fruiting peduncles 5-8 mm long; fruiting calyces strongly 5-angled, invaginated, 1.5-2.0 cm long, 1.0-1.5 cm wide, strigose. Mature berry ellipsoid, ca. 0.8 cm long, 0.6 cm wide, containing numerous golden foveolate seeds ca 1.5 mm in diameter.

**Distribution** (Fig. 12). Mexico and Central America in sandy soils along the Pacific Coast.

**Flowering.** Throughout the year.

**Uses.** Palmer reported in the label of his specimen 304 (US) that the species was sold in Acapulco's market throughout the year, but most probably he was referring to *P. philadelphica*, the common "tomatillo."

**Observations.** *Physalis minuta* is closely related to *P. cordata* from which it differs in its smaller size, mostly immaculate corollas and long petioles. *Physalis mimulus* appears to be a depauperate form of *P. minuta* from Socorro Island.

**Representative specimens examined:** COSTA RICA: GUANACASTE: Playa del Coco, 1 mi S of entrance along beach, 12 Oct 1975, Durkee 75-100 (F, MO). PUNTARENAS: Isla San Lucas, Golfo de Nicoya, 21 Oct 1984, Grayum 4274 (MO). MEXICO: COLIMA: Puente Palo Verde II between Cuyutlán and Armería, 9 Nov 1991, Sanders 11914 (TEX). JALISCO: Mpio. RIVAS: 2.6 km NW of entrance of San Martín on rd to Río Escalante, 3 Aug 1978, Stevens 9740 (MO). PANAMA: LOS SANTOS: beach at Montagre, 23 Dec 1966, Burch 1205 (F, NY).

**8. *Physalis missouriensis*** Mack. et Bush, Trans. Acad. Sci. St. Louis 12:84. 1902.

Type: USA: Missouri, Jackson Co., Red Bridge, 18 Sep 1901, Mackenzie 485. Holotype: K.K.Mackenzie Herb. (NY, not located); Isotypes: GH!, MICH, WIS.

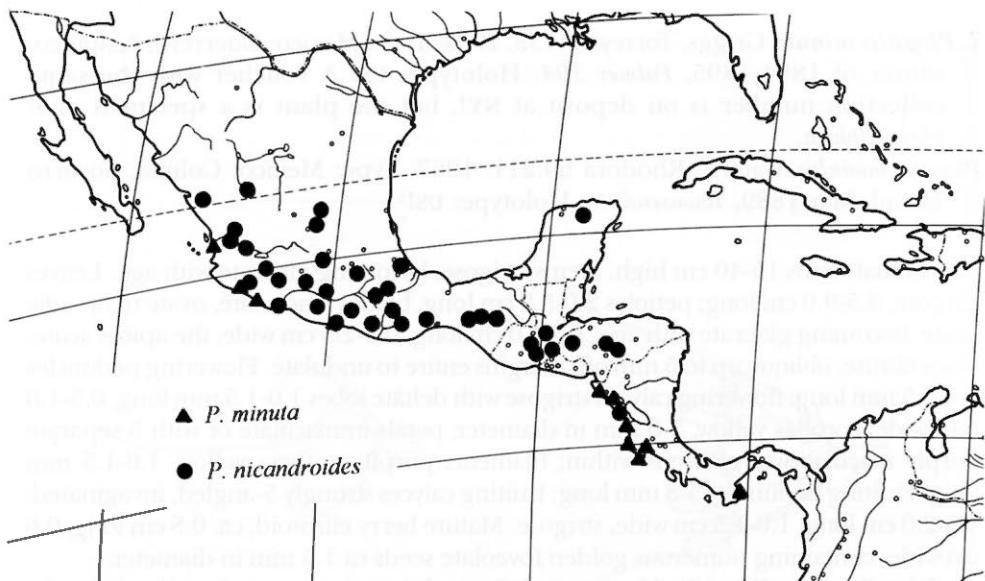

Fig. 12. Distribution of *P. minuta* and *P. nicandrodes*.

Annual herbs 15-40 cm high. Stems profusely branching, densely villous with multicellular glandular hairs 0.5-1.2 mm long. Leaves villous, 3.5-9.5 cm long; petioles 1-4 cm long; blades ovate to oblong, villous throughout but sometimes more densely so on the veins, 2.5-5.5 cm long, 2.0-4.5 cm wide, apices acute, bases obtuse to cordate, oblique in some specimens, up to 5 mm off, margins crenate. Flowering peduncles 2.5-6.0 mm long; flowering calyces villous with deltate lobes 1.5-2.5 mm long, 1.4-2.0 mm wide; corollas yellow, 7.0-9.5 mm in diameter, immaculate, pubescent within; filaments and anthers yellow, blue or blue-tinged, 0.8-1.0 mm long. Fruiting peduncles 5.5-9.0 mm long; fruiting calyces slightly 5-angled to terete, only slightly invaginated, 1.5-2.5 cm long, 1.5-2.0 cm wide, longer than wide, villous throughout. Mature berries spherical, 1.0-1.5 cm in diameter, containing numerous golden foveolate seeds ca. 2 mm in diameter.

**Distribution** (Fig. 13). Restricted to the United States in Arkansas, Kansas, Missouri and Oklahoma.

**Flowering.** From June to October.

**Observations.** *Physalis missouriensis* is readily distinguished from other species in the section *Epeteiorhiza* because of its almost terete fruiting calyces and immaculate corollas. Superficially, it resembles *P. angulata*, from which it differs in being densely villous-glandular throughout and having pedicels that do not exceed 1 cm in length.

Rydberg (1896) incorrectly identified this species as *P. lagascae* and considered it to belong to his series *Leptophyliae* because of its almost terete fruiting calyces. However, cpDNA data and SEM studies indicate that it is close to *P. pubescens*.

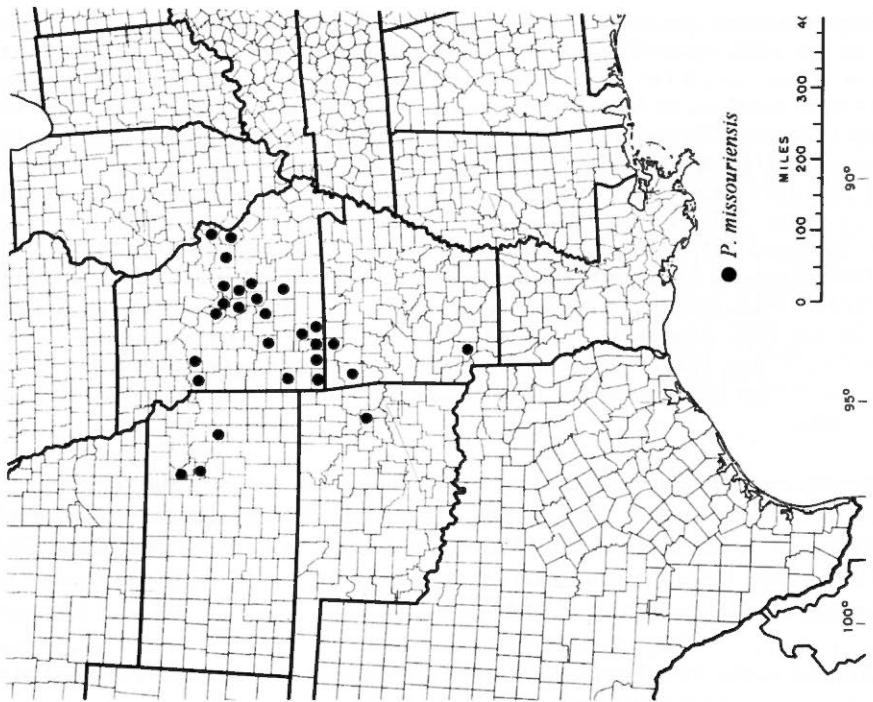

Fig. 13. Distribution of *P. missouriensis*.

**Representative specimens examined.** UNITED STATES OF AMERICA: ARKANSAS: Carroll Co., 23 Oct 1925, Palmer 29310 (MO). Washington Co., 27 Sep 1930, Moore 3008 (TEX). **9. *Physalis neomexicana* Rydb.**, Mem. Torrey Bot. Club 4: 325. 1896. *Physalis foetens* Poiret var. *neomexicana* (Rydb.) Waterf., Rhodora 60: 168. 1958. *Physalis subulata* Rydb. var. *neomexicana* (Rydb.) Waterf. ex Kartesz et Gandhi, Phytologia 72:89. 1992. Type USA: New Mexico [Santa Fe; cf. Gray 1849], 1847, Fendler 678. Lectotype: GH! Isolectotype: GH!

Annual herbs 10-50 cm high. Stems angulate and blue tinged at least at the top, densely covered with multicellular glandular hairs up to 1.5 mm long. Leaves 2.5-9.5 cm long, glandular-pubescent with multicellular hairs; petioles 0.5-3.5 cm long; blades ovate, 2.0-6.5 cm long, 1-5 cm wide, apex acute, base truncate, if oblique, only 3 mm off, margins crenate. Flowering peduncles 3.0-4.5 mm long; flowering calyces with acuminate lobes 2.0-3.5 mm long; corollas yellow, 0.8-1.3 cm in diameter, the petals with 5 separate dark blue maculations, pubescent within at insertion of filaments; filaments and anthers blue or blue-tinged, anthers 0.9-1.2 mm long. Fruiting peduncles 0.8-1.0 cm long; fruiting calyces strongly 5-angled, densely glandular-pubescent, 2-3 cm long, 2.0-2.5 cm wide, frequently as long as wide. Mature berry spherical, 1-2 cm in diameter containing numerous brown foveolate seeds 2.0-2.5 mm in diameter.

**Distribution** (Fig. 6). Restricted to the USA. in the Rocky Mountains in the states of Colorado, New Mexico, Arizona and Texas. The plant grows from 1500 to 2500 m in disturbed pinyon-juniper forest or disturbed short grassland.

**Flowering.** From June to September.

**Common names.** "Ground cherry", "tomate del campo".

**Observations.** When describing *P. neomexicana*, Rydberg included a flowering specimen from California (*Orcutt s.n.*, 1883 US) which has triangular calyx lobes, yellow anthers and long (3 cm) peduncles which I think does not belong to this species. The exclusion leaves *P. neomexicana* as a species endemic to the Rocky Mountains.

*Physalis neomexicana* and *P. patula* (formerly called *P. foetens*) are closely related, but they have distinct morphological characters and different distributions. Therefore, I treat them as different species.

**Representative specimens examined.** UNITED STATES OF AMERICA: ARIZONA: Apache Co., 2 Sep 1966, Barr 66-111 (ARIZ). Greenle Co., 14 Aug 1974, Pinkava PI2431 (NY). **10. *Physalis nicandroides* Schltdl.**, Linnaea 19:311. 1846. Type: Mexico: [Hidalgo] Atotonilco el Grande, Sep 1837, Ehrenberg 760 (HAL). Lectotype, selected here: HAL. Photolectotype: MEXU!

Annual herbs, 40-300 cm high. Stem unbranched, densely glandular-pubescent. Leaves glandular-tomentose, 7-19 cm long; petioles 2.5-5.0 cm long; blades of the growing season ovate to oblong, 4.5-14.0 cm long, 3-11 cm wide. Blades of the dry season associated with mature fruits oblong to elliptic, 3.5-4.0 cm long, 2-3 cm wide. Both kind of leaves with acute apex, base oblique up to 1 cm off, margin dentate to almost entire. Flowering peduncles ca. 6 mm long, flowering calyces glandular-pubescent with acuminate lobes 1.5-4.5 mm long, 0.5-0.8 mm wide; corollas pale yellow or whitish, 5-6 mm in diameter, glandular-pubescent outside, villous within, the petals with 5 greenish not strongly contrasting maculations; filaments dark blue or purple, anthers greenish, blue-tinged or blue, 1.4-2.0 mm long. Fruiting peduncles much thickened, 1.1-2.0 mm in diameter, 10-14 mm long; fruiting calyces strongly 5-angled with a leathery texture, 3.0-5.0 cm long, 2.0-4.5 cm wide, frequently as long as wide, glandular-pubescent. Mature berry spherical, 1.0-1.5 cm in diameter, glutinous, dark brown, containing numerous dark brown foveolate seeds ca. 2.5 mm in diameter.

**Distribution** (Fig. 12). From Durango throughout Mexico and S to Nicaragua. The plant grows in disturbed habitats of pine-oak forest, thorn forest and scrubland; from sea level up to 1900 m.

**Flowering.** From July to December. Collected with ripe fruits in January and February.

**Common names.** "Miltomate", "tomate zope" (Guatemala); "tomatillo", "vejiga de perro" (Honduras); "matapulgas", "tomate culebra", "tomate de perro", "tomatón", "yucu-quise" (Mexico).

**Uses.** Reported as a medicinal in Morelos; in Guerrero, the sticky leaves are laid over the floor forming a carpet that acts as an insect trap, especially for fleas; the fruit is occasionally eaten in Morelos (Mexico) and Guatemala.

**Observations.** *Physalis nicandroides* is closely related to *P. pruinosa*, from which it differs in having a thickened peduncle in fruit, colored anthers and hairs of the stem of a uniform size.

**11. *Physalis patula* Mill., Gard. Dict. 8:12. 1768.** Type: Mexico: Veracruz, without further locality, 1731, *Houstoun s.n.* Holotype: BM, Sloane collection. Photoholotype: BH! NY! OS!

***Physalis foetens* Poir. in Lam., Encycl. Méth. Bot., Suppl. 2:348. 1817.** Type: Mexico (?) but reportedly from "Peru", without further locality, 1803-1804, Bonpland s.n. Holotype: FI. The holotype was probably mislabeled as to locality, because the species is only known to occur in central Mexico.

***Physalis subulata* Rydb., Bull. Torrey Bot. Club 22:306. 1895.** Type: Mexico: Chihuahua, waste grounds, Guerrero, 8 Sep 1887, Pringle 1344. Holotype: GH!. Isotypes F! MEXU! NY! OKL!

Annual herbs, 10-150 cm high. Stems angular, densely glandular-pubescent, hairs 0.2-1.0 mm long. Leaves glandular-pubescent, 2.0-11.0 cm long; petioles 0.5-3.4 cm long; blades oblong to narrowly oblong or rhombic, glandular-pubescent, 1.5-7.5 cm long, 0.5-4.0 cm wide, apex acute, base attenuate or oblique up to 1.3 cm off, margin coarsely dentate. Flowering peduncles 2.5-9.0 mm long; flowering calyces glandular-pubescent with acuminate lobes 3-5 mm long, 1.5-2.0 mm wide; corollas yellow, 1.0-2.5 cm in diameter, petals immaculate or with 5 separate brown or blue maculations; filaments and anthers blue, anthers 1.5-2.7 mm long. Fruiting peduncles 7-14 mm long; fruiting calyces strongly 5-angled, 1.5-3.0 cm long, 1.0-3.0 cm wide, frequently as long as wide, glandular-pubescent. Mature berry spherical, 1.0-1.3 cm in diameter, yellow, containing numerous brown foveolate seeds ca. 2mm in diameter. The plant emits a strong offensive odor.

**Distribution** (Fig. 9). Restricted to Mexico, from Chihuahua to Oaxaca. The plant is a weed of dry highland habitats frequently associated with cultivated fields. It occurs from 900-2700 m in clay solil.

**Flowering.** July- December.

**Common names.** "Tomatillo", "hierba del zopilote", "jaltomate hediondo".

**Observations.** I am following Nee (1986) in the application of name *Physalis patula*. Although he later thought the name could be a synonym of *P. angulata* L. (Nee, pers. comm.), there is a description of the holotype at OKL "plant hairy throughout (probably viscid, as the pin-head glandular trichomes are very slender and small)...." which excludes this possibility. Waterfall, in the photograph deposited at OKL, interpreted the hair description as that of the fruiting stage of a mold. He made no reference to the name in his treatments.

*Physalis patula* has corolla which range from immaculate to maculate with five separate brown or blue blotches. The plants from Chihuahua with blue maculations and small corollas can be referred to as *P. subulata*, but the collections of Bye 9827 (UCR) have individuals with both forms, suggesting that they are but variations of the same plant. There are no other characters that correlate with the maculations.

I have not seen the holotype of *P. foetens*, but the collection Bourgeau 352 from Mexico City (BR, F, GH, OKLA! P, US!) was annotated by Poiret with that name, and gives a clear idea as to Poiret's species-concept.

**Representative specimens examined.** MEXICO: CHIHUAHUA: Mpio. Batopilas, S side of Barranca de Batopilas, W of La Bufa, 20 Oct 1980, Bye 10035 (UCR). OAXACA: Río Teposcolula, 500 m al S del poblado, 11 Jul 1981, García 527 (MEXU). PUEBLA: Xochitecatl cerca de Texmelucan, 16 Oct 1970, Boege 1543 (MEXU). QUERÉTARO: 8 mi E of Querétaro, 23 Aug 1961, Waterfall

16547 (F, US). TLAXCALA: Mpio. Hueyotlipan, 7 km al NW de San Siemón Xipetzingo, 11 Aug 1983, Williams 86 (CAS, F, MEXU). VERACRUZ: Mpio. Perote, outskirts of town on the NE side, 11 Dec 1985, Nee 32079 (NY, TEX).

**12. *Physalis porrecta*** Waterf., Rhodora 69:237. 1967. Type: Costa Rica: San José, vicinity of El General, Nov 1936, Skutch 2931. Holotype: US! Isotypes: GH, NY.

Perennial herbs, 30-100 cm high. Stems velutinous on one side, becoming glabrous with age, hairs sometimes glandular. Leaves velutinous to almost glabrous, 7-16 cm long; petioles velutinous, 2.0-6.5 cm long; blades elliptic to ovate, velutinous, 5-10 cm long, 3-8 cm wide, apex acuminate, base obtuse, margins dentate. Flowering peduncles 5-15 mm long, 1.8-2.0 mm wide; flowering calyces villous, 5 mm long, 2.5 mm wide, reflexed at anthesis; corollas yellow, 1.2-2.0 cm in diameter, petals with 5 brown, not strongly contrasting, maculations, pubescent within at insertion of filaments; filaments brown, anthers yellow, green or blue-tinged, 2.2-2.5 mm long. Fruiting peduncles 1.0-1.5 cm long; fruiting calyces glabrous, reticulated, strongly 5-angled, 3.0-5.5 cm long, 2-3 cm wide; always longer than wider, lobes 1.0-1.5 cm long. Mature berry spherical, ca. 1 cm in diameter.

**Distribution** (Fig. 5). Restricted to southern Mexico, Guatemala and Costa Rica, from 1500-2500 m elevation. The plant seems to form part of the native vegetation growing on volcanic soils.

**Flowering.** Throughout the year.

**Common names.** "Miltomate", "tomatillo" (Guatemala).

**Observations.** When describing *Physalis porrecta*, Waterfall included with this a flowering specimen from the lowlands of Oaxaca, Mexico (*Morton 2556 US*), which I think is best referred to as *P. cordata*. Another lowland specimen cited by Waterfall is one from Chiquimula, Guatemala (*Standley 73738 F*), a densely glandular plant referred here to *P. pruinosa*. These two exclusions leave *P. porrecta* as primarily restricted to highland habitats.

*Physalis porrecta* is closely related to *P. cordata*, from which it differs in possessing a velutinous vestiture, larger reticulated fruiting calyces and having a highland habitat.

**13. *Physalis pruinosa* L., Sp. Pl. 184. 1753.** Type: "Habitat in America", without further locality, date or collector. Holotype: LINN 247.13. Microfiche IDC 137! Photoholotype NY! (Fig. 14)

*Physalis maxima* Mill., Gard. Dict. 8:15. 1768. Type: Mexico: Veracruz, without further locality, 1730, Houstoun s.n. Holotype: BM, Sloane collection. Photoholotypes: BH! OKLA! US!

*Physalis cordifolia* Dunal in DC., Prodr.13:441. 1852. Type: from a cultivated plant in the Luggduno-Baravo Gardens, 1829, De la Roche s.n. Holotype: G-DC. Microfiche IDC 2098!

*Physalis nicandroides* Schlldl. var. *attenuata* Waterf., Rhodora 69:235. 1967. *Nom. invalid.*, no type was designated.

Annual herb 20-140 cm high. Stems pubescent with a mixture of long (2.0-2.5 mm) and short (0.5-1.0 mm) multicellular glandular hairs. Leaves 3.5-16.5 cm long, densely pilose with multicellular glandular hairs; petioles 1.0-6.5 cm long; blades 2.5-12.0 cm long, 2-9 cm wide, ovate to elliptic, pilose, the apices acute to acuminate, base cordate or truncate, sometimes oblique up to 1 cm off, the margins dentate to seldomly entire. Flowering peduncles 1.7-3.0 cm long; flowering calyces long-pilose, with acuminate lobes 2.5-6.0 mm long, 1.0-1.5 mm wide; corollas yellow 1.0-1.5 cm in diameter, the petals with 5 brown weakly contrasting maculations, glabrous or pubescent within; filaments blue, anthers always yellow 2.0-3.5 mm long. Fruiting peduncles not thickened, ca. 0.5 mm in diameter, 3.0-5.5 cm long. Fruiting calyces strongly 5-angled, 3.5-6.0 cm long, 2.5-4.0 cm wide, always longer than wide, glandular-pilose. Mature berry spherical, 1.0-2.5 cm in diameter, dark brown, glutinous containing numerous brown foveolate seeds ca. 2 mm in diameter.

**Distribution** (Fig. 15). From Chihuahua throughout Mexico and Central America (except Panama and El Salvador) south to Argentina. The plant is a weed growing at low elevations (up to 1400 m) in humid montane, oak or, more frequently, dry deciduous forest.

**Flowering.** From July to August in Mexico and Central America, collected with ripe fruits only in January-March. In South America, flowering from January to May.

**Common names.** "Farolito", "vejiga de perro" (Honduras); "miltomate", "tomatillo" (Guatemala); "tumatcho", "chipin sox" (huave) "tomate de culebra", "tomate de hoja", "tomate", "tomatillo", "tomatillo grande" (Mexico).

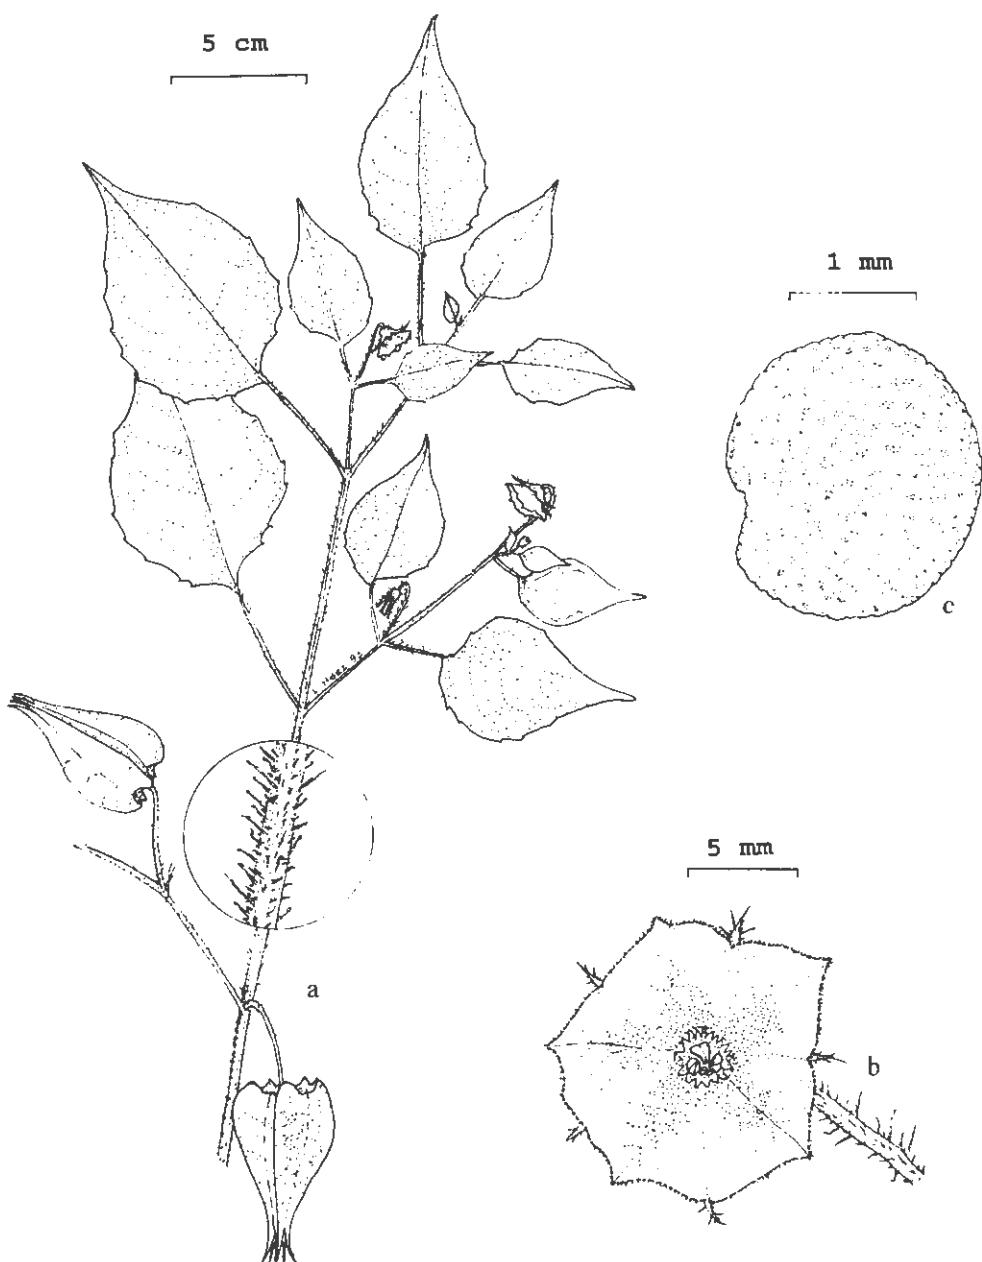

Fig. 14. *P. pruinosa* L.: a) branch with flowers, fruit, and a detail of the pubescense; b) flower; c) untreated seed.

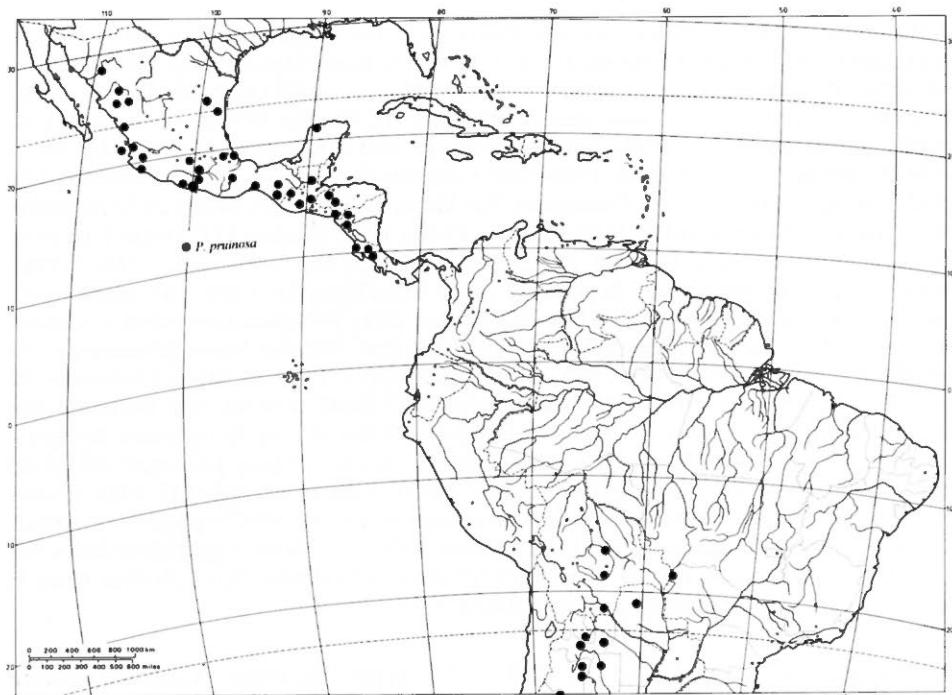

Fig. 15. Distribution of *P. pruinosa*.

**Uses:** The fruit is eaten in Mexico.

**Observations.** *Physalis pruinosa* is readily distinguished by its yellow anthers, long peduncles and a mixture of long and short stem-hairs. At maturity, the stems tend to become glabrous and the species may be confused with *P. nicandroides*. However, *P. pruinosa* does not have thickened fruiting peduncles.

Annual or biennial herbs 10-150 cm high, sometimes profusely branched. Stems variously pubescent, pilose to glandular-pilose with multicellular hairs up to 3 mm long. Leaves variously pubescent but mostly villous, 3-17 cm long; petioles 1.5-7.0 cm long; blades ovate to deltate, villous especially on the lower surface, mostly 2-10 cm long, 1-7 cm wide, apex acute to acuminate, base obtuse to truncate, if oblique, only up to 3 mm off, margins irregularly dentate to almost entire. Flowering peduncles 2-7 mm long; flowering calyces villous with triangular lobes 1.5-3.0 mm long; corollas yellow, 0.9-1.5 cm in diameter, the petals with 5 dark purple maculations, pubescent within at insertion of filaments; filaments and anthers purple or blue, yellow in a few specimens, anthers up to 2 mm long. Fruiting peduncles 5-10 mm long; fruiting calyces strongly 5-angled, 1.2-3.0 cm long, 1.8-2.5 cm wide, always longer than wide, villous throughout with multicellular hairs. Mature berry spherical, ca. 1 cm in diameter, green-purple to yellow, containing numerous brown foveolate seeds ca. 1.5 mm in diameter.

**Distribution** (Fig. 17, 18). From NE USA along the Atlantic Coastal Region, westwards to California and throughout the Mexican lowlands to Argentina in South America and the West Indies. The plant is a common weed of lowland habitats, mostly occurring from 0 to 900 m (up to 2700 m in Colombia), usually in sandy soils near rivers.

**Flowering.** From June to December in the USA except Florida where it flowers throughout the year, as in the rest of its range (Mexico, Central and South America).

**Common names.** "Sapo de gato" (Belize); "muyaca", "motojobo" (Bolivia); "canapú" (Brazil); "uva de perro", "uchuba", "uvilla" (Colombia); "mutios panga", "tsisin cucuna", "tomate de monte" (Ecuador); "huevo de tortuga", "miltomate", "huevitos", "tomatillo" (El Salvador); "miltomate", "tomatillo" (Guatemala); "batanto" (Haiti); "tomatillo" (Honduras); "cocostomat", "tomatillo", "miltomate", "tomate culebra" (Mexico); "topetón", "hierba de sapo" (Panama); "yutuimas", "bolsa mullaca", "bolsa mullaca blanca" (Peru); "ground cherry", "low hairy ground cherry" (USA); "topotopo" (Venezuela).

**Uses.** The fruit is eaten in Bolivia, Colombia, Ecuador, El Salvador, Mexico and Peru. It has been reported as medicinal in Ecuador (against measles) and in Peru.

**Observations.** Several names have been proposed based upon the variability of leaf shape and vestiture, but these characters are highly variable and taken together or singly do not appear to have any geographical correlations. Because of

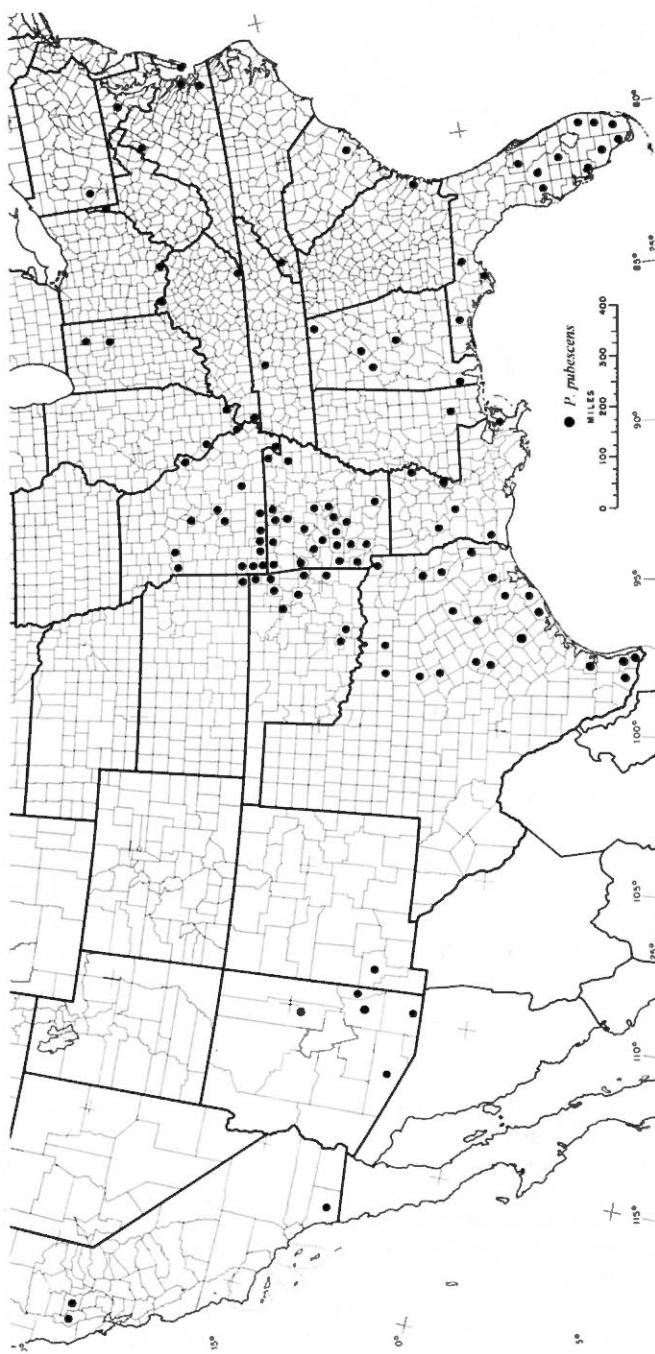

Fig. 17. Distribution of *P. pubescens* in the United States.

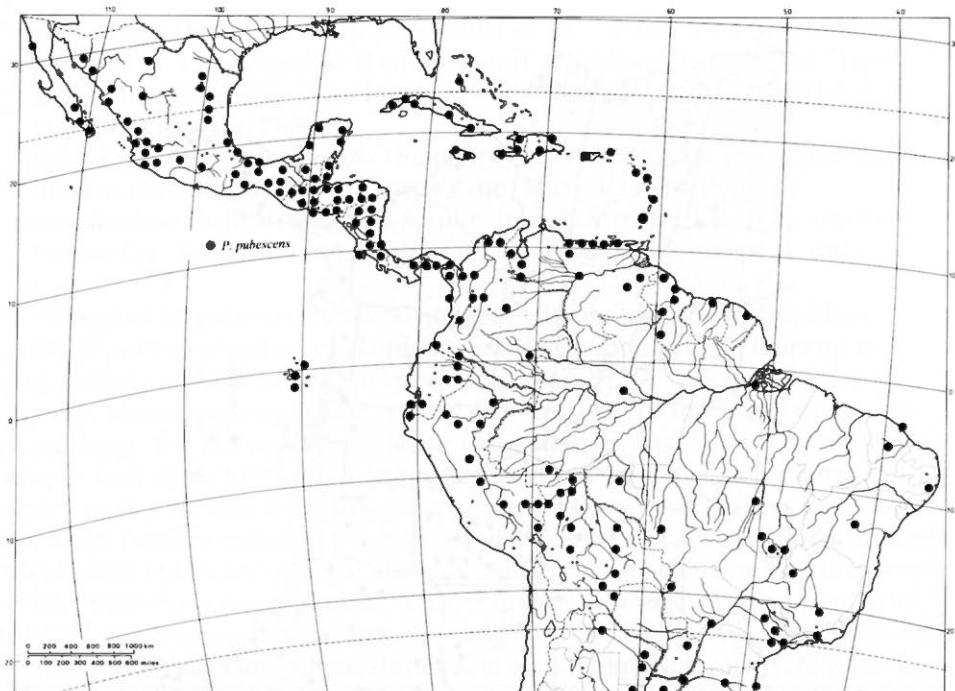

Fig. 18. *P. pubescens* in Mexico, Central America, South America, and the West Indies.

this variation and its behavior in the greenhouse, I have opted to treat the variation as part of a single widespread, rather heteromorphic species.

The characters that distinguish the species are the dark maculate corollas, purple to blue anthers, and the villous, strongly 5-angled fruiting calyces. A few South American collections (marked below) have yellow anthers and can be referred to as *Physalis neesiana*. However, yellow anthers, though rare, are found elsewhere in the range of *Physalis pubescens* (e.g. in Arizona, Bertelsen 91-080 ARIZ). Since such specimens do not exhibit any other character that might differentiate them, I cannot recognize *P. neesiana*.

### DOUBTFUL AND EXCLUDED NAMES

*Physalis greenei* Vasey et Rose, Contr. U.S. Natl. Herb. 1:18. 1890. *Nomen nudum*, no description was provided.

*Physalis hirsuta* M. Martens et Galeotti, Bull. Acad. Roy. Sci. Bruxelles 12:132. 1845.

Based on *Linden* 254, a voucher could not be located at GENT. The curators located *Linden* 255 (*Physalis coztomatl* Dunal) and *Linden* 256 (*P. pubescens*). The description suggests it could be conspecific with *P. pubescens*, but the name could have priority over other names if this is a good species.

*Physalis linkiana* Nees, Linnaea 6:471. 1831. No specimen was cited in the original description. From the description, the plant seems to be close to *Physalis angulata* from which it was said to differ in having longer peduncles. Any possible type at B would have been destroyed during World War II.

*Physalis surinamensis* Miq., Symb. Fl. Surinam. Linnaea 17. 1844. No specimen was cited in the original description. The description is of a hirtellous plant from Surinam with immaculate corollas. I have not seen any specimen referable to this name, either at U or elsewhere.

### ACKNOWLEDGMENTS

This revision was part of my PhD. dissertation, partially supported by Conacyt and the B.L. Turner Fund. L. Hernández, J. Saunders and J. Panero tested the key; B.L. Turner and M. Nee reviewed earlier versions; L. Hernández, P. Delprete, and N. Webber provided the illustrations. R. Jones and L. Hernández reviewed the final version. Two anonymous reviewers and Fernando Chiang kindly reviewed the manuscript and their suggestions greatly improved the paper. I am grateful to the curators of the following herbaria for the loan of their specimens: ALBU, ASUF, ARIZ, CAS, ENCB, F, G, IEB, MEXU, MO, NY, OKL, OKLA, TEX-LL, UNM, US and VPI. The curator at HAL kindly provided a photograph of the type of *P. nicandroides*, the curator at GENT kindly searched for the type of *P. hirsuta*.
